Executive Summary

Most promising novel certification process options improving safety were identified within previous ASCOS work. Avoiding unnecessary change and recognising the good approaches already in place, an improved process for safety performance monitoring was developed using recommendations/requirements of ICAO and EU for SMS, as well as, Total Aviation Safety approach. The elaborated monitoring process can be implemented within any of the novel certification options - be it enforcing existing rules, demonstrating safety by achieving objectives or the cross-fertilisation.

A long-term ICAO Global Aviation Safety Plan (GASP) [7] objective already recommends the implementation of predictive risk modelling systems that assure safety in a real-time and collaborative decision-making environment. For the near-term and mid-term GASP expects organisations to implement Safety Management Systems (SMS) and to have appropriate performance indicators, to verify the causal factors and use the alert levels. In the EU, the suggested by ICAO SMS is to be implemented together with a much wider Management System (MS) "to ensure compliance with these essential requirements for airworthiness, and aim for continuous improvement of this system" [24]. The required approach recommends transition from quality management to SMS to develop and to apply skills and practices that account for Human Factors, and continuously reinforce compliant behaviour and risk-based decision-making. The most advanced EASA rules concerning suggested improvements has been issued for aircrew (Part-ARO) and operations (Part-ORO). Yet, the requirements for other aviation sectors will be transposed from generally applicable Part-ARO and Part-ORO.

ASCOS performance based monitoring process (refer to 2.1) uses the Continuous Monitoring Approach (CMA) as an integral part of the stakeholders' life cycle processes for the purpose of the Safety Assurance SMS component.

The most promising data sources (refer to 3.3 and 3.4) are raw data obtained by Flight Data Monitoring (FDM) or Flight Operations Quality Assurance (FOQA) fed into a central repository. Either of two approaches to FDM as the source for the SPIs are recommended:

- 1. Central collection of predefined FDM parameters/events
- 2. Central collection of raw flight data

The required significant resources and organisational effort (incompatibility of ECCAIRS) along with the arising concerns (impracticability of raw data, stakeholders' doubts to give up control on their data, 'big brother' syndrome) were the reasons for postponing direct FDM and FOQA data use in favour of indicators (first approach). [43] Also, flight simulator as a source of data for actual Safety Assurance was briefly considered (refer to 3.5).

ASCOS method is based on monitoring of 63 Safety Performance Indicators (SPIs) grouped at four levels (Technology, Human, Organisation, System of organisations) referring to different stakeholders of the Total Aviation System (Aircraft, Airframe, Board Systems, ATC/ATM, Airlines, MRO, etc.). [46]

Ref:ASCOS_WP2_IoA_D2.3Page:12Issue:1.0Classification:Restricted

The SPIs were linked to causal factors – precursors (refer to Appendix A). The precursors were, then, linked to the stakeholders (refer to Appendix C) and together with the SPIs monitoring could be part of the novel certification process. Since the SPIs do not measure safety directly, quality of the results depends on the inductive reasoning. Information born by the continuously monitored and semi-continuously measured SPIs is transformed assuming the uniformity of nature. The transformation presupposes that a sequence of events in the future will occur as it always has in the past. For a simplified example a past SPI target level of safety (TLS) exceedance linked to precursor 'lack of English proficiency' will, ceteris paribus (no change in English skill), cause the TLS exceedance again. The 'comorbidity' with other SPIs TLS exceedances may lead to one of the Operational Issues. Thus, the historical, lagging SPIs integrated with precursors and Operational Issues possess predictive information and enhance Safety Assurance.

The integration was elaborated in previous ASCOS work [44] - the method of SPI-precursor linking steps. The mentioned 'linking steps' were called 'metaprocess to safety performance monitoring' and they go beyond the monitoring itself, but provide a tool to apply it (refer to 2.2, Appendix B).

An example of a way of using SPIs to assure safety was presented (refer to 2.3).

The control of SPIs no. 1-46 assumes:

- setting Target Levels of Safety (TLS) of SPIs for current period to reach planned objectives (e.g. average and standard deviation from previous year SPIs)
- reacting to every exceedance of TLS by the Safety Manager and the team by development of response plans with the help of precursors
- implementing response plans by the Management and monitoring their results

A group of SPIs (no. 47-63) deal with the System of organisations level. Their application, however, were not recommended due to non-conformity (refer to 4). [43] On the other hand, Safety Assurance within Total Aviation System (TAS) at this level could be controlled by monitoring of supervised organisations safety performance using periodically (e.g. monthly) aggregated SPIs no. 26-44. The underperforming organisations would be identified using descriptive statistics - atypicality distance and hazards could be mitigated using similar to other levels approach (refer to 4.1).

It is assumed that ASCOS performance monitoring is implemented within the framework of management of change (PDCA, refer to 2.1.3) together with other SMS components (refer to 2.4). The SPIs can be promoted, implemented and reported to the ECCAIRS repository using ECCAIRS taxonomy based occurrence reporting system with some minor additions to the taxonomy (refer to 3.2). In most cases, information needed for ASCOS SPIs, is, more or less, already required by the EU directive 2003/42/EC on occurrence reporting in civil aviation (refer to Appendix D). [56]

Appendix E and F provide some general, basic information on ICAO oversight audits, EASA standardisation as well as on the aviation safety databases.

1 Introduction

The main objective of ASCOS is to develop novel certification process adaptations and supporting safety driven design methods and tools to ease the certification of safety enhancement systems and operations, thereby increasing safety. To achieve this, six measureable and verifiable objectives are defined, each to be addressed in one specific dedicated Work Package (WP):

- 1. To develop safety based certification process adaptations based on analysis of existing certification and rulemaking process and evaluation of different possible new approaches;
- 2. To develop a method and supporting tools for multi-stakeholder Continuous Safety Monitoring, using a baseline risk picture for all the parts of the total aviation system;
- 3. To develop a total aviation system safety assessment method and supporting tools that can be used for safety based design of new systems, products and/or operations;
- 4. To apply proposed certification process adaptations to design systems in case studies, so as to illustrate how the adaptations can be of benefit to operators and manufacturers;
- 5. To validate key results: a) new certification approach, b) method and tools for Continuous Safety Monitoring, and c) all the supporting safety based design systems and tools.
- 6. To inform air transport stakeholders on the proposed certification approach through promotion workshops, supported by exercises and an e-learning web-site environment.

As it was mentioned above, the objective of WP2 - Continuous Safety Monitoring is to develop a method and supporting tools for multi-stakeholder continuous safety monitoring, using a baseline risk picture for all parts of the total aviation system. The stakeholders include air navigation service providers, operators, and manufacturers.

Such a continuous monitoring approach to standardised implementation is also advocated by ICAO [7, 2] and SM ICG [34].

1.1 Task objective

In the context of developing a method and the supporting tools for multi-stakeholder continuous safety monitoring, the objective of this specific deliverable is to develop an improved process for safety performance monitoring in which Safety Performance Indicators (SPIs) for each stakeholder will be linked with precursors for all the main operational issues for commercial air transport operations.

The objectives of this task are also to investigate:

- How Continuous Monitoring Approach (CMA) can be used as integral part of the life cycle processes
 for continued airworthiness of aircraft, and maintenance of certificates for air navigation service
 providers, operators, and manufacturers?
- If and how flight data obtained by Flight Data Monitoring (FDM), Flight Operations Quality Assurance (FOQA) can be used to enhance the safety benefits of a multi-stakeholder CMA in aviation?

Ref:ASCOS_WP2_IoA_D2.3Page:21Issue:1.0Classification:Restricted

1.2 Research approach

The research starts with a theoretical overview of a process for safety performance monitoring and measuring. The process is one of the twelve elements comprising the ICAO SMS framework and it is part of the ICAO SMS component – "Safety Assurance". The safety assurance process provides confidence that the SMS is operating as designed and that it is effective. In particular it helps the organisation to verify its safety performance, to ensure that the risk mitigation measures are effective and to identify and assess changes and manage the associated risks.

A process of safety performance monitoring and the method improvement is based on the feedback known in the literature as the Deming Circle or PDCA Cycle (refer to 2.1.2).

The purpose of this study is to provide methods needed to implement the process. Special emphasis is given to determine the links between SPIs and precursors for all the main operational issues of commercial air transport operations (refer to 2.2) and the use of data from FDM or FOQA in continuous safety monitoring (refer to 3.4).

1.3 Structure of the document

This document is organised as follows:

- Section 2 contains a description of the process for safety performance monitoring including ICAO and regional principles, process organisation and the relationship with other processes in the SMS framework;
- Section 3 focuses on Safety Data collection, analysis and exchange. This section provides criteria for data quality and a description of a Safety Databases;
- Section 4 contains ASCOS System of organisation level SPIs potential contribution to it;
- Section 5 includes conclusions and recommendations.

The document includes the following appendices:

- Appendix A contains a summary of the analysis of the link existing between precursors and SPIs;
- Appendix B includes complete details of Steps 1 to 8 defined by ASCOS D3.2[44] to identify the links;
- Appendix C is the list of ASCOS precursors associated to the stakeholders;
- Appendix D is the list of ASCOS SPIs confronted with EU directive 2003/42/EC on occurrence reporting;
- Appendix E provides detailed information on ICAO USOAP CMA background and perspectives and a description of the EASA Standardisation process;
- Appendix F provides overview of aviation safety databases.

Ref:ASCOS_WP2_IoA_D2.3Page:22Issue:1.0Classification:Restricted

1.4 Definitions

Bow-Tie diagram. Such a diagram illustrates a hazard, an undesirable event, safety events and potential outcomes, and risk controls put in place to minimise the risk. Bow-Tie method involves asking a structured set of questions in a logical sequence. [58]

Deviations. Procedural or flight path deviations. A precursor type that may be observed randomly, but could become combined and, thus, result in a major occurrence. [48]

Lagging indicator. Metrics that measure safety events that have already occurred including those unwanted safety events that are to be prevented (SM ICG). [34]

Leading indicator. Metrics that provide information on the current situation that may affect future performance (SM ICG). [34]

Management System (MS). A management system of an air operations pursuant to EC 216/2008 including specific requirements in terms of safety and corresponding to the size, nature and complexity of operator. [19]

Precursor. Identifiable event that may be used as early warning for known or potential hazards. [46]

- Events identified and currently monitored, for which the potential to become hazardous is known to be significant.
- Events not known yet, but for which induced risks may have been initially underestimated therefore not
 enough reduced, neglected or even unidentified up till now, unless revealed by an actual occurrence of
 the hazard.

Safety Assurance. One of four components of the ICAO recommended SMS. These are processes and activities undertaken by the service provider to determine whether the SMS is operating according to expectations and requirements. [6]

Safety Management System (SMS). A systematic approach to managing safety including, the necessary organizational structures, accountabilities, policies and procedures. [2]

Safety Manager. An accountable manager with a direct safety responsibility required within Management System of organisation. [19]

Safety Performance Indicator. A data-based parameter used for monitoring and assessing safety performance. [2]

Safety performance target. The planned or intended objective for safety performance indicator(s) over a given period. [2]

Ref:ASCOS_WP2_loA_D2.3Page:23Issue:1.0Classification:Restricted

Safety performance. A State or a service provider's safety achievement as defined by its safety performance targets and Safety Performance Indicators. [2]

Safety Policy and Objectives. One of four components of the ICAO recommended SMS. It outlines the principles, processes and methods of the organization's SMS to achieve the desired safety outcomes. [6]

Safety Promotion. One of four components of the ICAO recommended SMS. It encourages a positive safety culture and creates an environment that is conducive to the achievement of the service provider's safety objectives. [6]

Safety Risk Management. One of four components of the ICAO recommended SMS. It systematically identifies hazards that exist within the context of the delivery of its products or services. [6]

Safety risk. The predicted probability and severity of the consequences or outcomes of a hazard. [2]

Safety. The state, in which risks associated with aviation activities, related to, or in direct support of the operation of aircraft, are reduced and controlled to an acceptable level. [2]

Service providers. The term "service provider" refers to the organizations listed below [7, 2]:

- a) air traffic services (ATS) providers in accordance with ICAO Annex 11 (including AIS, CNS, MET and/or SAR services);
- b) approved maintenance organizations providing services to operators of aeroplanes or helicopters engaged in international commercial air transport, in accordance with ICAO Annex 6, Part I or Part III, Section II, respectively;
- c) approved training organizations in accordance with ICAO Annex 1 that are exposed to safety risks related to aircraft operations during the provision of their services;
- d) operators of aeroplanes or helicopters authorized to conduct international commercial air transport, in accordance with ICAO Annex 6, Part I or Part III, Section II, respectively;
- e) operators of certified aerodromes in accordance with ICAO Annex 14;
- f) organisations responsible for the type design or manufacture of aircraft, in accordance with ICAO Annex 8.

State Safety Programme (SSP). An integrated set of regulations and activities aimed at improving safety. [2]

Uneventful events. A precursor type including events that already occurred. Although the events are being uneventful, they could have a more severe outcome under different circumstances. [48]

Uniformity of nature. The principle used to justify inductive reasoning in scientific research presupposing that a sequence of events in the future will occur as it always has in the past.

Ref:ASCOS_WP2_IoA_D2.3Page:24Issue:1.0Classification:Restricted

2 Process for safety performance monitoring

2.1 ASCOS Safety Assurance process

A long-term ICAO Global Aviation Safety Plan (GASP) [7] objective is the implementation of predictive risk modelling systems that assure safety in a real-time, collaborative decision-making environment by the Block Upgrades strategy. For the near-term, GASP identifies two objective groups:

- Effective Safety Oversight effective implementation of a fundamental safety oversight in States lacking it;
- Safety Management and Predictive Risk Modelling full implementation of State Safety Programs
 (SSP) in the rest of States followed, in the mid-term, by Safety Management Systems (SMS)
 implementation in organisations.

To facilitate the planning process, the objectives are supported by Safety Performance Enablers: Standardisation (uniformity in implementation), Collaboration, Resources and Safety Information Exchange. The ICAO guidance material suggests [6], that an effective implementation of SSPs and SMSs requires complementing the existing prescriptive safety management with a performance-based approach.

In cooperation with ICAO [11], the EU regulations went further extending the requirements beyond SMS towards an integrated, proportional, flexible and binding across the sector total aviation management system that includes the ICAO SMS components (Safety Policy and Objectives, Safety Assurance, Safety Risk Management and Safety Promotion).

Aligned to global and regional near and mid-term aviation safety objectives and requirements, ASCOS proposes two processes enhancing Safety Assurance component of the SMS.

Firstly, there is a metaprocess that serves as a tool for identification of links among quantifiable Safety Performance Indicators (SPIs), Operational Issues and precursors [44]. It is assumed that metaprocess is done once during ASCOS to identify initial relations, but it would be also done later to update links and identify more precursors for future improvements (refer to 2.2).

Secondly, there is a process for implementation of the Safety Assurance enhanced by ASCOS precursors within a Management System. According to ICAO SMS Manual [6] section 5.3.73 recommendations, ASCOS builds upon the Appendix 6 to Chapter 5 of the ICAO manual by enhancing the SMS component with the metaprocess findings (the links and precursors) (refer to Appendix A).

Ref:ASCOS_WP2_IoA_D2.3Page:25Issue:1.0Classification:Restricted

2.1.1 Performance-based requirements

ICAO requirements

The calls for implementation of SSP and SMS provisions recommended to global civil aviation in a consolidated effort have lasted at least since 2010 [2]. In 2011, ICAO began the transition of its auditing programme, the USOAP [7], to a Continuous Monitoring Approach (CMA). (refer to Appendix E) The CMA aims to provide a continuous report of effective implementation of SARPs identifying safety deficiencies, assessing associated risks, developing assistance strategies and prioritizing improvements. The main interaction is rooted in safety data collection, analysis and exchange. It is played by two actor categories:

- aviation authorities (overseeing service providers according to the SSP)
- service providers (managing safety through their own SMS).

The ICAO manual specifies the following performance-based requirements for a SSP/SMS [6]:

- The regulator needs to have a process for continuous monitoring of individual product and service
 providers' safety performance. Additional new performance-based processes introduced and duly
 accepted/approved by the regulator, should have appropriate performance indicators developed for
 monitoring such performance-based processes. Such process specific indicators, proposed in the
 project, may be viewed as complementary indicators to the higher level SMS Safety Performance
 Indicators.
- 2. The safety performance outcome from the introduction of performance-based element(s) within or complementary to a SMS framework should not be worse off than an existing purely prescriptive regulatory framework. Where there is a degradation of the system's performance, the service provider should work in conjunction with the regulator to verify the causal factors and take actions as appropriate. Such actions may include necessary modification of the performance-based requirement itself or where necessary, restoration of basic prescriptive requirements.
- 3. Monitoring and measurement of a performance-based process should be done through appropriate performance, quality or safety indicators that continuously track the performance of that process. Parameters for such performance tracking may be occurrence outcomes, deviations or any event types that reflect the safety, quality or risk level of the process. A data trending chart should be used to track such outcomes. The alert level setting will effectively serve as the demarcation line between the acceptable trending region from the unacceptable region for a safety indicator.
- 4. The assessment of a performance-based process would require the assessor to be aware of the context of that process element within its overall regulatory framework as well as the complexity of the audited organization (the acceptability of a hazard reporting system or acceptability of proposed target alert levels for a performance-based process). It may involve more (than in the prescriptive method) interaction, monitoring, negotiation and objective judgment for the auditor.

Ref:ASCOS_WP2_IoA_D2.3Page:26Issue:1.0Classification:Restricted

Regional requirements

The SMS suggested by ICAO is not compulsory in European Union. In fact the regulations require a much wider Management System (MS) "to ensure compliance with these essential requirements for airworthiness, and aim for continuous improvement of this system" [24]. Yet, European regulations follow ICAO recommendations (e.g. ICAO Annex 13 Chapter 8 Accident prevention measures) and foster regional arrangements in using standardized formats to facilitate safety data exchange. Regional coordination is, also, planned by the EASA European Aviation Safety plan (EASp) within a system of two-way dialog where SSPs of the Member States are supposed to, gradually, get aligned to EASp and follow the paradigm shift to pro-active approach [28].

A new Management System is the subject of a stand-alone approval, its implementation is assessed as part of the normal initial certification and oversight processes. The existing organisation certificates are generally "grandfathered", i.e. they are automatically approved. The MS "components" are, also, subject to the procedures of existing bilateral agreements. A standardized approach has clearly defined lines of responsibility and accountability according to safety policy in identification of hazards, evaluation and mitigation of risk by competent personnel and recorded within documentation system. Emerging civil aviation regulations [18,19] place obligations on enabling transition from quality management to SMS with Safety Manager or Safety Review Board responsibilities complementary to and as significant as e.g. finance management that includes, among others, performance monitoring, too.

The assessed "riskiness" of an organisation and its risk management capabilities influence the level of oversight applied, i.e. the oversight programme is established based on the assessment of performance-influencing factors, organisational changes and other safety performance indicators. The requirements of emerging regulations favour service providers showing a high-performing MS and clear safety leadership.

The MS requirements are recommended to all certified organisations allowing for maximum interoperability. The general principle is that all organisations that may have an impact, directly or indirectly, on the safety of flight, need to do their part in terms of hazard identification, safety reporting, risk assessment and mitigation. EASA-promoted "Integrated management" enables managers to recognise and take into account all significant influences on their organisation (in case of SMS – Safety Policy and Objectives, Safety Risk Management, Safety Assurance and Safety Promotion):

- The newly forged and binding EU rules for authorities within Part-ARO and Part-ARA [18,19], indirectly address EASp/SSP implementation in order to avoid any impacts on plans already implemented in terms of: oversight functions;
- personnel qualification;
- handling safety-critical information;
- authorisation;
- surveillance;
- resolution of safety concerns.

Ref:ASCOS_WP2_IoA_D2.3Page:27Issue:1.0Classification:Restricted

According to the regulations competent authorities are obliged to establish their MS that include "Internal audit and safety risk management". It is recommended to use best practices for record keeping and running register of approved organisations and envisioned for standard planning cycle of 24 months (with possible extension to 36 or 48).

As a part of a single network the requirements for authorities are interpreted and applied in a standardised manner [15], not less and not more than required by Community law, and taking "into account ICAO Doc 9735 — the USOAP continuous Monitoring Manual" (refer to Appendix E).

MS of an organisation pursuant to the regulation EC 216/2008 is a total aviation management system. It means a service provider needs an integrated, proportional, flexible approach and the same requirements are binding across the sector. Therefore, MS required by European Union regulations exceeds the scope of SMS described by ICAO Annexes.

The most advanced EU legislation concerning the SMS standards in MS is in the area of aircrew and operations regulations (Part-ORO and Part-ORA) [18, 19]. The "soft law" of Acceptable Means of Compliance and Guidance Material of Subpart GEN to the regulations provide suggested details. The philosophy, in general, requires developing and applying skills and practices that account for Human Factors, and continuously reinforce compliant behaviour and risk-based decision-making.

The Air Navigation Systems of Single European Sky States are bound by the Common Requirement of a performance scheme [14] to improve overall efficiency (including safety) in line with the Performance Framework of the European ATM Master Plan. Previously the ESARRS (EUROCONTROL Safety Regulatory Requirements) and the use of tools and guidance provided by EUROCONTROL (e.g. the TOKAI system for the investigation of occurrences) were considered as best practice or a minimum requirement. The improvement of the ANS Risk Picture is developed under SESAR WP16-Safety Management and Safety Assessment [40].

Until the entry into force of the corresponding EU Regulation, the national rules in place (following ICAO Annex 14) apply to the management systems (that include SMS) of aerodromes.

The EU rulemaking concerning Part-21 organisations (Design and Manufacturing), as well as, Part-M (maintenance), Part-145 (continuing airworthiness management organisations) and Part-147 (maintenance training) focus on compliance to quality system and they have not yet been amended in terms of the new Management System requirements. Yet, the requirements will be transposed from generally applicable Part-ARO and Part-ORO developed for aircrew and air operations.

2.1.2 A management system and ASCOS enhancement

The main elements of aviation organisation current management system emulate typical management system requirements:

- · documented policies and procedures;
- sufficient and adequately qualified personnel, including the obligation to plan the availability of personnel;

Ref:ASCOS_WP2_loA_D2.3Page:28Issue:1.0Classification:Restricted

- nomination of management personnel for the different areas of activity;
- adequate facilities and accommodation;
- a function to monitor compliance of the management system, including nomination of a person or group of person responsible for the compliance monitoring function;
- the need to ensure that certification and oversight tasks performed on behalf of the competent authority are conform to the applicable requirements;
- a system to identify changes that affect the management system and to take action to ensure it remains effective;
- a system of record-keeping to ensure traceability of activities performed.

ASCOS proposes a method for enhancing the management system by safety performance monitoring focused on Total Aviation System. The method is based on monitoring of 63 SPIs [43] linked to causal factors – precursors (refer to Appendix A) and offers a way of using them to assure safety (refer to 2.2.4). The control of SPIs no. 1-46 assumes:

- setting target levels of SPIs for current period to reach planned objectives
- reacting to every exceedance by the Safety Manager and the team by development of response plans using identified precursors
- implementing response plans by the Management and monitoring their results

The SPIs no. 47-63 deal with the system of organisations level and are offered for further consideration as they require more changes to the current situation (refer to 4.4).

The method allows for transforming historical lagging signals and using them together with leading signals in pro-active prevention. The transformation presupposes that a sequence of events in the future will occur as it always has in the past. E.g. past SPI TLS exceedance linked to precursor 'lack of English proficiency' will cause the exceedance again and concerted with other SPIs exceedances may lead to one of the Operational Issues. Thus, the historical, lagging SPIs integrated with precursors and Operational Issues (refer to 2.2.3 and Appendix B) possess predictive information and enhance Safety Assurance. The integration was elaborated by previous ASCOS work [44] - the method of SPI-precursor linking steps. The mentioned 'linking steps' were called 'metaprocess to safety performance monitoring' and they go beyond the monitoring itself, but provide a tool to apply it.

The reported SPIs aggregates could be further analysed following the inductive reasoning in terms of trends.

Moreover, data points (as SPIs, FDM data, or even precursors if collected, even partially) could be placed into distinct categories, often of a qualitative nature (precursors) and thus fall into a category, commonly described as "discrete choice" data. An entire class of models is available to analyse discrete choice data. For example variance-based probability models like the logit models:

- ordered logit (which recognises an inherent ordering in the categories)
- multinomial logit (which do not recognise any ranking among choices)

Ref:ASCOS_WP2_IoA_D2.3Page:29Issue:1.0Classification:Restricted

Provided large enough random samples are available, such probability models of occurrence and factors sensitivity analysis could be applied to examine Operational Issues from a statistical perspective.

The 2012 FAA report [54] represents a first in the US, regression-based analysis of occurrence data (10,408 runway incursions collected by the FAA Runway Safety Office RI database). The results are suggestive rather than definitive. For example, controller incidents appear to be more severe on average. The report concludes further investigation specifically in understanding the frequency of incursions and improvements to the severity measure.

2.1.3 Process organisation

The proposed organisation of the ASCOS process for safety performance monitoring is based on the Deming cycle (Plan-Do-Check-Act) [34]. The steps defined in the process are as follows:

1. Designation of responsibilities

A company implementing a Management System defines general aspects of the organisation that need to be measured and controlled using a subset or total set of the ASCOS SPIs. The designated personnel responsible for introduction of the SPIs should include safety and quality management specialists with practical experience. Timeline and milestones need to be elaborated and regularly monitored.

2. Review of safety policy and objectives

Safety management policies need to be reviewed in the context of current EASp/SSP documents. Each Safety Performance Indicator should have a target or threshold above which action will be taken. In addition the organisation may have objectives regarding the implementation of SPIs. Mitigation plans based on the precursors linked to SPIs are to be developed and ready to be used or modified and use when TLS of the indicator is exceeded. Documentation of the assumptions that are taken into account when assessing risk of hazards should be created for future reviews. For other details concerning a mitigation plan development refer to, for example, the EHEST SMS Emergency Response Plan [31].

3. Definition of indicators and their specifications

The SPIs specification needs to be elaborated, including metadata allowing for determining its meaning as well as data quality and source. Quantitative indicators have advantage over qualitative ones in that they can be compared and allow detecting trends and deviations from the expected performance. This feature is important to the ASCOS method in transforming historical lagging SPIs into leading signals. Yet, qualitative indicators can be used to enrich later analyses and in support of the quantitative SPIs.

4. Determining data requirements

Data already available in the organisation need to be reviewed and checked with the needs to determine what additional data is needed and how it can be obtained to satisfy SPIs reporting. The key consideration is data quality, especially reliability and validity.

Ref:ASCOS_WP2_IoA_D2.3Page:30Issue:1.0Classification:Restricted

5. Collection of information

Having chosen the indicators, the next step is to establish data collection process, determine the sources, how the data is stored, format in which it will be reported.

6. Analysis of the results

Since the SPIs do not measure safety directly, quality of the results depends on the inductive reasoning. Assuming the uniformity of nature, presupposing that a sequence of events in the future will occur as it always has in the past, the SPIs, integrated with precursors and Operational Issues in an elaborated metaprocess presented below (refer to 2.2) possess information that could be used to proactively improve the organisation's processes and procedures to enhance the safety and quality of the operation. In other words, by the mentioned assumption, a leading SPIs (i.e. comprehensive analysis of the organisations grouped in System of organisations level of SPIs) and the rest, historical, lagging SPIs are logically located a priori to the EASp Operational Issues (GCOLs, LOC-I, CFIT, MACs, REs). When SPIs' TLS are exceeded, an adequate, previously prepared mitigation plan is to be confronted with the "real" (relevant in the considered situation and period) precursors discovered during investigation (supported by e.g. FDM data) and modified. The "real" precursors lists are the ASCOS precursors (refer to Appendix C), but their particular validity is verified during investigation.

Bow-tie models contain events which can be quantified or associated with FDM parameters and occurrence reports from voluntary reporting programs

However, a different, more real-time or automated approach to provide Safety Assurance than the ASCOS process.

FDM data is continuously updated (on the contrary to the semi-continuously updated SPIs), but even FDM data provides lagging information when it finally becomes available, together with the SPIs, to Safety Manager and his team for analysis and, possibly, risk mitigation in the future.

7. Response to findings

The management reviews the precursors regularly and make decisions to take corrective actions if needed. The pool of the identified "real" precursors should be treated as a kind of "soft" primary cause, directing the Safety Manager towards the best response to arising risks after further investigation. Implementing the mitigation plans should be undertaken in correspondence to Safety Risk Management (risk avoidance, reduction, transfer, assumption, and risk exposure segregation) and its tools (e.g. Bow-Tie diagram). [58] The results and actions taken should be communicated to the staff. Failing mitigation plans are evaluated, improved and implemented again. The SPIs are periodically reported to a European data repository.

8. Evaluation and correction of SPIs

The SPIs and their specification should be reviewed regularly. Validity of used indicators should be evaluated with experience gained as well as upcoming changes in internal and external environment of the organisation.

Ref:ASCOS_WP2_IoA_D2.3Page:31Issue:1.0Classification:Restricted

After a chosen period, for example the one corresponding to the EASA standard planning cycle, the SPIs-precursors linking list should be updated (refer to 2.2) and the management system should be reviewed.

By implementation of the process, the Safety Assurance component will be transitioned from prescriptive to performance-based safety management rooted in quantifiable SPIs and enhanced by the ASCOS precursors (refer to Appendix A) and their method of application within MS.

2.2 Internal structure of the metaprocess of SPIs and precursors links identification

To be more informative on the representation and the evaluation of the emerging/future risks, the semi-continuously updated SPIs need to be linked to concrete information where the significant problems arise and for what reasons. 'Semi-continuous update' meaning periodical aggregation of the SPIs events, refers to ASCOS D2.1 [43]. ASCOS D3.2 [44] prepared a metaprocess to enable the safety performance monitoring and its continuous improvement within a MS. The metaprocess identifies links between SPIs and precursors leading to the Operational Issues.

2.2.1 Safety Performance Indicators

A list of SPIs was defined in ASCOS D2.1[43] at four different levels:

- Technology (lagging);
- Human (lagging);
- Organisation (lagging and leading);
- System of organisations (lagging and leading).

Leading indicators are identified through comprehensive analysis of the organisations. They are associated with organisational and managerial issues which are difficult to quantify and whose relation with accident risk is not so obvious. In order to facilitate the quantification, the comparability and the automatic detection of safety occurrences, the proposed framework of SPI deliberately excluded any leading indicators, giving priority to the lagging indicators, due to the fact that it is easier to both measure and analyse them based on objective criteria. [43] A System of organisations level (including leading SPIs) is considered in Section 4.4 ASCOS safety performance monitoring process for system of organisations (refer to 4.4).

The lagging SPIs concern already happened events and represent actions previously taken by the aviation system operators in the context of the EASp Operational Issues [43]. Their use is limited to the analysis of historical records with the aim of prevention of future Operational Issues.

Figure 1 presents considerations on the availability of emerging safety information in relation to a timeline for possible action. During the post flight operation phase the Safety Manager and his team use the process as described above (refer to 2.1.3), that includes lagging indicators, historical information and the precursors, and prepare a reaction to provide Safety Assurance of future operations. They are not able to provide a real-time

Ref:ASCOS_WP2_loA_D2.3Page:32Issue:1.0Classification:Restricted

reaction to emerging issues in flight operation (i.e. while flying, taxiing, taking off, landing), because these data are not available to them at the time of event occurrence.

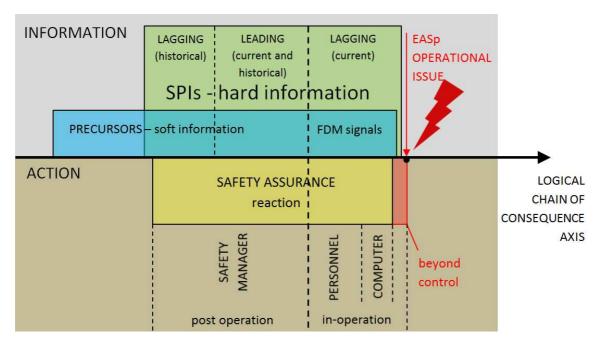

Figure 1 Safety Assurance using SPIs and precursors

A more direct impact on Safety Assurance while in the flight operation phase remains "in the hands of" operating personnel and automatic systems control. FDM data is continuously updated (on the contrary to the semi-continuously updated SPIs), but even FDM data provides lagging information when it finally becomes available, together with the SPIs, to Safety Manager and his team for analysis and, possibly, risk mitigation in the future.

The SPIs were linked to the Base Events of the Causal Model for Air Transport Safety (CATS) V0.1 for ASCOS grouped in the EASp Operational Issues:

- Runway Excursions (RE) while take-off and while landing
- Mid-Air Collisions (MAC)
- Controlled Flight Into Terrain (CFIT)
- Loss Of Control In flight (LOC-I)
- Ground Collisions (GCOL)

2.2.2 Precursors

A list of precursors, characterised in ASCOS D3.1[46] and presented in ASCOS D3.2[44] (about a dozen as examples), was massively populated, up to 500 different precursors (refer to Appendix C). The new precursors, including occurrences (uneventful events), as well as deviations were identified using the following rules:

Ref:ASCOS_WP2_loA_D2.3Page:33Issue:1.0Classification:Restricted

- a. Precursors should be identifiable at one of 4 levels corresponding to the SPIs levels:
 - Human (human errors, lack of adherence to procedures, pilot incapability, etc.)
 - Technology (system failures, malfunctions etc.)
 - Organisations (e.g. workload distribution)
 - System of organisations (requirements definition, regulations, etc)
- b. Precursors should be semantically separable (there should not be precursors which cover the same event, even partially)
- c. Set of defined precursors should exhaust the specified range of factors identified as influencing the safety (e.g. adverse weather)

2.2.3 Application of the method for linking precursors to SPIs

Please refer to ASCOS D3.2 for a detailed description of the method [44]. Step 1 was completed by ASCOS D3.2. Starting from Step 2 of the method precursors are gradually incorporated into the model. During the most intensive effort of the Step 6 they were linked to the Base Events of the Causal Model for Air Transport Safety (CATS) V0.1 for ASCOS.

- Step 1 Association of CATS Event Sequence Diagrams (ESDs) to EASp Operational Issues
- Step 2 Association of precursors (occurrences, deviations) and defences/controls when possible.
- Step 3 Linking of updated precursors list (occurrences, deviations) and CATS ESDs initiating events.
- Step 4 Linking of defences/controls updated list and CATS ESD number
- **Step 5** Linking of defences/controls updated list and CATS ESD safety barriers
- Step 6 Linking of precursors and CATS Base Events

Steps 3-6 were carried out in D3.2 [44] for the seven CATS ESDs(#1,2,3,4,5,9,10) as an example. These Steps were continued and completed until ESD #37 (for Step 6) in this document, ASCOS D2.3.

- Step 7 Linking of CATS ESD Base Events and 63 ASCOS SPIs
- **Step 8** Linking of precursors and SPIs. This Step was finalized by merging Step 6 table and Step 7 table results at the same, corresponding ESDs Base Events. The result was later refined by the application of a conditional sum of sets of precursors to eliminate the uninformative duplicates of links (for more details please refer to Appendix A in this document).

The resulting table of SPIs, precursors and indicated Operational Issued is located in Appendix A (Appendix A.pdf).

Ref:ASCOS_WP2_IoA_D2.3Page:34Issue:1.0Classification:Restricted

2.3 An example of ASCOS enhanced Safety Assurance

For the purpose of this example, the analysis was limited to one lagging SPI only. Yet, individual SPIs are not expected to be very informative. Usually several of the SPIs have to be considered and looked upon from the Management System perspective as well as using statistical inference (refer to 4.1).

Consider a simplified example of Safety Assurance within MS using one SPI – Technology level SPI no 7 "Rate of landing gear system failures/flight" (refer to Appendix D). The event measured by SPI7 may lead to Runway Excursion during landing.

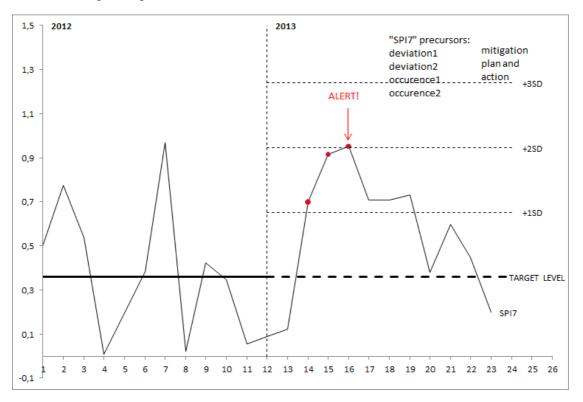

Figure 2 Safety performance monitoring, one SPI example (X-axis: periods=months since implementation of MS, Y-axis: SPI7 rate in 1000s monthly aggregated at a service provider level)

As suggested by ICAO SMS Manual, a point average of 2012 SPI7 data was chosen (refer to Figure 2) to use as a TLS for 2013 safety plan of the organisation. The alert of growing risk of Runway Excursion during landing was triggered during 16th period by 3 consecutive points above the 1 SD (Standard Deviation) line.

The practical approach to respond to this exceedance could for example follow the Eight Disciplines Problem Solving approach [13] (8D: Plan; Use a Team; Define and describe the Problem; Develop Interim Containment Plan; Determine, Identify, and Verify Root Causes and Escape Points; Choose and Verify Permanent Corrections (PCs) for Problem/Non Conformity; Implement and Validate Corrective Actions; Take Preventive Measures; Congratulate Your Team). Another approach to such an exceedance can be found within the safety

Ref:ASCOS_WP2_loA_D2.3Page:35Issue:1.0Classification:Restricted

management toolkit like the one suggested by EHEST for Non-Complex operators [31]. However it could be generalised as presented in the Table below.

SPIs ALERT!		SPIs		Mitigation		Mitigation plans		Effects
(TRL		precursors		plans		implementation:		evaluation
exceedance),		investigation:		validation:				(consecutive
Risk of:								period SPIs
								acquiring):
Operational	>>>	precursors:	>>>	Plan1	>>>	Validated plan1	>>>	SPI1
Issue1		Occurrence1		Plan2		Validated plan2		SPI2
Operational		Occurrence2		Plan3		Validated plan3		SPI3
Issue2		Deviation1						
		Deviation2						SPIn

Table 1 The generalised example of practical use of the ASCOS SPIs and precursors

The ASCOS precursors linked to SPI7 give the Safety Manager of the organisation starting points to adapt to the current situation and to improve the mitigation plans in case of the SPI7 target exceedance which were prepared during the Management System implementation (or change) phase at the beginning of the planning cycle. The mitigation plan modification is adapted through the Root Cause Corrective Action (RCCA) meetings that provide resources, necessary soft and hard knowledge, as well as analytical and decisive manpower to "eliminate the causes of nonconformities". The Safety Manager initiates a series of RCCA meetings inviting managers of every department of the organization to explain the identified hazard and to develop a mitigation plan with the hazard response team. Managers or delegated workers (equipped with adequate powers) join the hazard response team. The team gathers timely information and sends it to the Safety Manager, who uses it to flag which precursors of the ASCOS model were "real" (relevant) in the considered situation and period (see example below).

SPI7: Rate of landing	ASCOS model precursors –	Post investigation "real"
gear system	uneventful events (occurrences)	precursors
failures/flight	Hard landing	Chief of pilots: Yes, a group of pilots confirm several hard landings
	Bounced landing	No
	System failure affecting aircraft configuration, controllability and/or flying qualities	No
	Tailwind or crosswind landing with tailwind and/or crosswind component(s) in excess of applicable limit(s), either intentionally or unknowingly	No
	Convective weather / turbulence / windshear / crosswind encounter during approach and landing	No
	Convective weather encounter	Operations Officer: Yes, the surprise convective weather has been encountered many times for last three months.
	(more)	

CDIZ Data affaration	ACCOC	David 1
SPI7: Rate of landing	ASCOS model precursors –	Post investigation "real"

Ref:ASCOS_WP2_loA_D2.3Page:36Issue:1.0Classification:Restricted

gear system	deviations	deviations
failures/flight	Flaws in maintenance technician / airworthiness specialist / requirements definition process and/or training methodology	No
	Maintenance technician / airworthiness specialist - Inadequate workload distribution	No
		Fleet Roster Officer: Yes, flying personnel is exhausted. We have not enough crew to
	Pilot tiredness - Inadequate workload distribution	keep rotations going in our net.
	Flaws in pilot requirements definition process and/or training methodology	No
	Flaws in design of maintenance processes	No
	Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements	No
	Flaws in manufacturer quality control process	No
	High energy approach due to lack of adequate planning or due to challenging design of STAR (high fix-crossing-altitudes,) or challenging ATC instructions (late descent, vectors, altitude or speed restrictions,)	No
	Late deceleration and configuration set-up for approach and landing	No
	Unstabilized final approach (high, fast, steep,)	No
	Lack of adherence to emergency procedures	No
	Lack of adherence to SOP in terms of approach and landing	No
	Lack of adherence to the SOP in terms of PNF flight parameters / situation monitoring or / and passive contribution to the PF duties	No
	Tailwind component above limit	No
	Aggressive maneuvering / overcontrolling	Cpt. Smith: Yes, I happened to overcontrol the B737 during approach at EPWA, several times, lately.
	Lack of adherence to ICAO Annex 14 SARPs. Poor or inefficient bird hazard reduction procedure	No
	(more)	

Table 2 An example of SPI7 associated precursors list and the post investigation "real" precursors

The precursors are a list of potential causes that are evaluated in the team to determine if they are relevant in the current case and if positive, mitigation is developed for the "real" precursors.

As it is seen in the example above, a living positive safety culture (revealing crucial information voluntarily) is an important condition of Safety Assurance enhanced by ASCOS safety performance measurement method. The culture needs to be supported by organisations' Management Systems and Safety Promotion in particular.

The RCCA team uses post investigation "real" precursors (Table 2), ASCOS defences and corresponding regulations to modify the mitigation plan and presents it at the next RCCA meeting. E.g. "In order to avoid the arising safety risk the hazard response team suggests the following:

- organise additional training for pilots focusing on Aggressive manoeuvring / overcontrolling during landing adjust personnel skills to Part-ARA requirements;
- new flying personnel hire positive Financial Department opinion;

Ref:ASCOS_WP2_IoA_D2.3Page:37Issue:1.0Classification:Restricted

• improve weather warning systems on board – adjust aircraft to Continuing Airworthiness Requirement".

The management considering the post-investigation safety mitigation plan can take action and can issue adequate instructions. However, some of the discovered safety issues may go beyond service provider level requiring Civil Aviation Authority assistance (e.g. renegotiation of bilateral agreements due to different levels of ICAO requirements conformity among States to be flown from/to, changes to obligatory training procedures). At the end of a certain period the organisation reports all its SPIs levels to a European database. The undertaken actions allow for SPI7 reduction aiming at current TLS. If, despite undertaken actions, operational issues occur anyway, then RCCA should be repeated. The SPIs may be redefined at the end of the next planning cycle. The alert levels should be reset during next planning cycle. Early signals of an operational issue (i.e. historical lagging SPIs trends and historical/current leading SPIs trends) allow for avoiding the operational issues by developing and implementing adequate actions. The safety level is monitored and preventive/corrective action is taken in order to prevent that an Operational Issue (accident or incident) occurs.

2.4 Relationship with other components of the SMS framework

The Safety Assurance component addressed in this document needs to be implemented within a Management System and needs to support the remaining components of the SMS [44]:

- Safety Policy and Objectives it is a senior management commitment to embed ICAO SMS SARPs in a
 way to ensure compatibility within the framework of an organisation activity. Safety Assurance
 provides feedback signals for improvements of policies and objectives as well as regulations.
- Safety Risk Management it includes hazard identification, safety risk assessment and the implementation of appropriate mitigation measures. Service providers ensure that the safety risks encountered in aviation activities are controlled in order to achieve their safety performance targets. In other words it enables decision makers to set priorities by the hazard identification based on a combination of reactive, proactive and predictive safety data collection methods and to decide if organisation needs to mitigate risk, to schedule performance of a safety assessment or to perform no action. Controlling risk is done by placing barriers. [58]
- Safety Promotion managers lead by example, training and effective communication in conversion of
 an organisation to and in maintaining a positive safety culture. In the Safety Assurance context it
 could be the following: voluntary and non-punitive divulging information about off-nominal safety
 related events, clear separation between acceptable and unacceptable actions, effective, quick and
 smooth adaptation to mitigation, willingness to change, protection against political pressure, cultural
 conventions, chance and 'big brother' syndrome. The better the safety culture, the more efficient the
 Safety Assurance will be.

Ref:ASCOS_WP2_IoA_D2.3Page:38Issue:1.0Classification:Restricted

3 Safety Data Collection, Analysis and Exchange

3.1 Criteria for data quality

The type of safety data to be collected may include SPIs concerning number of accidents and incidents, events, non-conformance or deviations and hazard occurrences. Data collection needs to use existing reporting infrastructure, notably the ECCAIRS reporting system. The quality of the data that is used to enable effective decision making must be considered throughout SSP and SMS development and implementation. The proposed data collection is a proactive approach that would complement the reactive approach. To determine how safe the system needs to be, Safety Objectives (SOs) are specified on the basis of an overall TLS. A SO is a qualitative or quantitative statement that defines the maximum frequency or probability at which a hazard can be accepted to occur. To determine how safe the system can be, the SOs are apportioned into Safety Requirements (SRs) for each of the hazards and causes underlying an event for which a SO is specified. This may subsequently be used by manufacturers and operators as guidance in a certification process. ASCOS's proposed method follows exactly the same process, but derives the proposed TLS, SOs, and SRs from the existing quantified CATS. A possible approach for the setting of Safety Objectives and Safety Requirements to be used in the design phase is as follows:

- 1. Define the system, product or operation (including assumptions, limitations, etc);
- 2. Identify relevant incident/accident and accident avoidance scenarios;
- 3. Select Event Sequence Diagrams (ESDs) from CATS and the IRP that are valid for the system, product or operation;
- 4. Modify or update the selected ESDs, if deemed necessary;
- 5. Develop and quantify ESDs for scenarios unique to the new system, product or operation;
- 6. Select, modify and/or develop and quantify FT for each of the events in the ESDs;
- 7. Derive a proposed TLS of Safety for the overall risk probability;
- 8. Derive SOs for each end-event in all the ESDs for the new system, product or operation;
- 9. Derive Safety Requirements for each of the hazards and causes represented in the FTs.

Key point: In any process the quality of the input (in this case data) will have a direct bearing on the potential quality of the output. Prior to implementation, ASCOS should take into consideration the less than perfect quality of input that is likely to be encountered. The analysis is supplemented by data quality criteria [35]:

1. Data validity

The validity of data means it is correct and in the absence of errors. The lack of validity is misleading. Errors are likely to appear due to mistakes in data entry which is difficult to avoid in gathering large volume of data.

2. Data completeness

Ref:ASCOS_WP2_IoA_D2.3Page:39Issue:1.0Classification:Restricted

Completeness measures how much of the data is gathered versus how much of the data is needed for specific purpose (e.g. analysis). The needs must be defined to assess data completeness. Achieving full completeness may by expensive and is not always possible.

3. Data Timeliness

Timeliness means that the data is up-to-date. The more recent the data, the better. In optimal situation, the real-time data are available.

4. Data Availability

Data availability in time measures how much data can be obtained when needed. Redundancy can improve data availability.

5. Data Accuracy

The accuracy measures to what extent the data describes real objects or events. Accuracy depends on the means used to measure objects.

Collected data need to be created and stored in a standardized format to facilitate data exchange and analyses for continuously monitored safety.

3.2 Evaluation of feasibility and implementation issues related to proposed processes of safety performance monitoring in ECCAIRS Reporting System

3.2.1 Feasibility of the proposed processes of safety performance monitoring

As indicated in the scope of the ASCOS project the tool for Continuous Safety Monitoring to be developed in sub task 2.4 will focus on measuring the SPIs defined in the other subtasks of Work Package 2 in ECCAIRS compatible repositories. Given this particular scope, the high number of SPIs and the limited areas of concern for which SPIs have been developed some considerations are made regarding the implementation of the tool(s):

- The tool(s) should be focused on monitoring occurrence data from an ECCAIRS 5 compatible repository. Which actual repository to be used in the long term and how access to this repository can be obtained are questions considered outside the scope of sub task 2.4. This approach avoids that possibly cumbersome political/strategic discussions on this subject will consume resources better spent in the development of the tool.
- Considering that the SPI definitions may be subject to reconsiderations and alterations, the tool to be
 developed should be kept as flexible as possible so can be easily deployed using the same
 mechanisms for a different (set of) SPIs possibly in other areas of concern.

Ref:ASCOS_WP2_loA_D2.3Page:40Issue:1.0Classification:Restricted

 Where possible usage will be made of existing analytical means which are part of, or linkable to, the ECCAIRS Reporting System. Building on top of existing and usable technologies will offer the best efficiency. The approaches and algorithms used should not be restricted to an ECCAIRS environment and will be described on a general level.

• Given that the limited timeframe of the ASCOS project, the amount of new occurrence data available for analysis will be small. For this reason the tools to be developed should be able to also use historical data to perform a monitoring of SPIs during a to be defined time frame in the past.

Indicators to be considered within the context of ASCOS have been defined in Deliverable 2.1 "Framework Safety Performance Indicators" and are available in the list of SPIs at the end of this document (refer to Appendix D). Note: the breakdown by areas of concern is that used in Deliverable 2.1.

An evaluation of the proposed indicators was carried out to determine to what extent they could be developed taking into account the current ECCAIRS taxonomy. Based on this evaluation, the issues related to the following indicators were observed:

- Technical related to the failures of critical systems other than installed on aircraft such as rate of aerodrome de-icing facilities failure/flight. This indicator specifically refers to the "failure of the de-icing facilities" but airport ground radar or navaids systems also can be pointed. The current ECCAIRS taxonomy does not provide for a classification of the failure of the facilities but only for a classification of an issue related to de-icing which could be either an issue with the facilities or with the use / operation of the facilities and related services.
- Human Rate of deviation from localizer/approach: The current ECCAIRS taxonomy does not have a
 specific descriptive factor that covers deviation from localizer. A more general descriptive factor
 "glide path" is at hand.
- Human Rate of ground spoiler failure to deploy/landing. The text would indicate that there was a failure of the spoiler system while the context would indicate that the crews failure to arm / deploy the spoiler should be captured. It is recommended to clarify the text of this indicator.
- Human Rate of navigational errors which result in a loss of separation with terrain/flight. This
 indicator required the presence of a navigation related event followed by an event indicative of a near
 CFIT (e.g. too close to ground etc). The issue here is to ensure that the occurrence data is properly
 structured providing not only the event related to navigation but also the aspect of "near CFIT".
- Human Rate of incorrect flight crew response to TCAS RA warnings/warning: ECCAIRS provides for
 the recording of a TCAS warning related event, the incorrect crew reaction, however, is covered with
 a different attribute "crew reaction to TCAS". The two attributes need to be combined for the
 development of this indicator.
- Human Rate of incorrect flight crew response to EGPWS warnings/warning: Similar to the TCAS
 warning and related action, the EGPWS warning itself is captured as an event, while the details of the
 crew's reaction to the warning are captured in a different attribute. The two attributes need to be
 combined for the development of this indicator.

Ref:ASCOS_WP2_loA_D2.3Page:41Issue:1.0Classification:Restricted

- Human Rate of loss of separation events/flight. While the ECCAIRS taxonomy provides an event type
 for the "loss of separation", consideration should be given to limit this to those "loss of separation"
 events where there was a risk of collision.
- Human Rate of misuse of automation events: A definition the term "misuse of automation" is required.
- Human Rate of near-stall events/flight: This is interpreted as occurrences in which a genuine stall warning was triggered.
- Human rate of ground movement errors/flight. It is understood that here navigational issues of aircraft moving on the ground are implied. Considering that the suggested rate related to "flight" errors of movements of ground vehicles will not be counted.

Based on the evaluation, the number of those events that are used to calculate the rates of the proposed SPIs listed above can be counted using ECCAIRS taxonomy based occurrence reporting system. Some minor additions to the taxonomy – providing more detail in respect to the "deviation from glide slope" - could be suggested to the ECCAIRS Taxonomy Working Group. This should not be a major issue, as only additional detail under an existing event type would need to be added to the taxonomy, thus no re-classification of old data would be required.

In order to develop related rates, access to matching exposure date (number of flights) would be required. Sources for such data would need to be developed. As mentioned already in ASCOS D2.1[43], it should be investigated whether the EASA Data Warehouse could be used for this purpose.

In principle, it would thus be feasible to develop and maintain the proposed indicators. Nevertheless, issues related to implementation continue to exist and would need to be resolved.

3.2.2 Implementation issues related to proposed processes of safety performance monitoring in ECCAIRS Reporting System

Access to relevant data

The proposed safety indicators are based on occurrence and matching exposure data.

In order to count the relevant event types listed above, an ECCAIRS compatible database is required into which all relevant occurrences are inserted. In principle such database is at hand – the European Common repository (ECR). In it occurrences from all States of the European Union and the associated States (Norway, Iceland, Switzerland and Liechtenstein) are integrated continuously. At the time of writing this report, occurrence data integration is based on EC 1321/2007[20]. The dissemination of integrated data is governed by EC 1330/2007[21].

Both regulations are under review. Based on the draft, the ECR will continue to exist in the future. Access will be simplified for some actors in the aviation system. Additional measured aimed at improving the quality of the reported data are also being considered.

Ref:ASCOS_WP2_loA_D2.3Page:42Issue:1.0Classification:Restricted

In the context of ASCOS, it would be safe to assume that the occurrence data from the ECR will be available for analysis to an entity entrusted to carry out the work of maintaining the proposed SPIs.

In regards to access to matching exposure data, the matter appears to be more complicated. Data in the ECR not only relate to the occurrences occurring within the Reporting States, but also to aircraft registered in or operated by the Reporting States. Thus, while for the EU States data on the number of commercial flights in Europe should be available through the related database in EUROCONTROL, the matching information regarding the number of flights carried out outside of Europe is not known.

There are commercial exposure data providers that collect data on the number of flight by aircraft type, but such commercially available data is not complete as not all operators provide related information. Estimates may be available only. Other complications arise from copyright considerations. It would be left to the entity entrusted to maintain the safety indicators to make the appropriate arrangements to obtain access and to integrate the various exposure data sources for analysis.

Data quality

By definition data analysis is based on data. Thus, if no data is present or the data reported is incomplete or incorrect, the analysis will fail to provide reliable results.

Data issues that would have an impact on ASCOS would relate to the non-reporting of occurrences, the incomplete reporting of relevant background data, such as the aircraft type, and the inconsistent reporting of the occurrence scenarios through occurrence categories and event types as well as issues related to the duplication of reporting resulting from the various interacting players having their own reporting systems but integrating their individual reports into a common repository.

Given that that reporting of mandatory occurrence data is governed by legislation, one could assume that the law abiding aviation industry will provide the reports required. Nevertheless, it would help to instil confidence in the process if the reporting of a State to the ECR would be included in the EASA standardisation activities.

The issue of incomplete or late reporting is known to the rule makers and the industry. Since years, the reporting to the ECR has been monitored and gaps in reporting have been publicized by the JRC and EASA. One of the goals of the proposed new regulation on occurrence reporting is to "Ensure that data issued from reported occurrences and stored in the national databases and in the ECR <u>are complete and of high quality</u>" [23]. It seeks to improve the data quality by making several data attributers "mandatory", i.e. they have to be reported. One of the attributes to be reported would be the "event type".

Should the European Parliament and the Council agree with this approach, the presence of event types would be ensured. This is important as there have been suggestions that the classification of the event types should be dropped and their analysis be replaced by text mining approaches. In regards to the work of developing and monitoring SPIs in ASCOS, dropping the reporting of event types would prevent any related analysis as well as the development of related SPIs and would thus prevent the process of performance monitoring from being implemented.

Ref:ASCOS_WP2_IoA_D2.3Page:43Issue:1.0Classification:Restricted

The issue of multiple reporting of a given occurrence through multiple occurrence channels is known and is, at the time of writing this document, addressed by a working group of the ECCAIRS Steering Committee. It's report on progress is found on the ECCAIRS portal[22]. The technical issues appear to be well known, a political decision may be required to move forward.

In regard to the standardization of the reporting of event types (assuring that the same events are reported by different sources for similar occurrence scenarios), much work remains to be done. Experience working with data in the current ECR shows that some States consistently vary from the recommended approach to classification. For example, a "factor" should only be reported in ECCAIRS when it was relevant to the occurrence. The fact that a spoiler was not deployed should be reported only, when the deployment of the spoiler would have been required. Factors should not be used to simply record the position of flight controls in an operational occurrence. Other examples relate to some States not providing the complete story in the sequence of events by failing to report the last event (e.g. the collision with the ground after a loss of control or the go-around after an unstabilised approach).

Several mitigating measures could be considered: Data verification tools could be deployed to check the comprehensiveness and consistency of the reporting at the time of the initial entry of the data into the occurrence databases. Such tools have been developed by the EASA and are made available on the ECCAIRS portal. They should be further enhanced and their use should be promoted.

The ECCAIRS software already has the facility to develop and apply data quality rules.

In addition, samples of classifications for various occurrence scenarios should be prepared that clarify the required event type sequences for standard occurrence scenarios. Such work could build on the work done by EASA in developing coding guidelines for occurrence reporting.

3.2.3 Mapping exposure data to data in occurrence reports

In the development of rates, occurrences need to be mapped to related exposure data. For rates related to aircraft, the number of movements of a given aircraft type needs to be linked to the occurrences in which this type was involved. Development of such mapping has been complicated in the past because of the various ways in which aircraft types have been described.

For the Air Traffic Services, the aircraft is usually described via the ICAO type designator [3]. In aircraft registers aircraft are frequently identified using the CAST-ICAO Common Taxonomy Team taxonomy [8]. This approach has also been followed in ECCAIRS.

The aircraft type designator is provided for each aircraft in the CAST-ICAO reference database, but there are type designators for which CAST-ICAO does not (yet) have a related record and there are many entries in the CAST-ICAO reference database which share the same type designator. Thus, based on type designators, it is not always possible to obtain from an air traffic related flight database the number of flights for a given aircraft make model series.

Ref:ASCOS_WP2_IoA_D2.3Page:44Issue:1.0Classification:Restricted

It should be noted that recent developments of type designators and developments of the CAST-ICAO reference database have been coordinated. Thus, while the problem of obtaining the matching exposure data exists for aircraft presently in service, it may be reduced or eliminated for new aircraft entering service.

3.2.4 Process considerations

In the above it has been demonstrated that the data required to develop the proposed SPIs are available and that, notwithstanding certain issues, such SPIs can be developed. The actual development of related tools is subject of work package D2.4 and will not be addressed here.

While thus the data issues have been addressed, the issues of which entity will be entrusted with the development and maintenance of the indicators, for which products the indicators will be built, what information will be fed back to the industry and what actions will be taken based on the indicators have not been addressed. These issues remain to be resolved.

In this context, one should consider whether indicators should be built to monitor the aviation system in Europe as a whole or whether indicators would be built that monitor those elements of the aviation system affected by ASCOS separately from those based on legacy methods. In any event, given the slow introduction of changes in the aviation system, the effects of ASCOS will not be seen for some time with any confidence in the data as a large number of occurrence reports will be required to obtain some statistical confidence.

3.3 The use of data from the Flight Data Monitoring (FDM), Flight Operations Quality Assurance (FOQA) in continuous safety monitoring

3.3.1 Background

At present airline operators collect large volumes of operational data that are recorded on the aircraft's quick access recorders. On modern aircraft thousands of variables are recorded as function of time. Such data are routinely analysed using a so-called Flight Data Monitoring (FDM) programme. FDM programmes assist an airline operator to assess their operational risks. This section is about the possibilities on how flight data obtained by FDM can be used to enhance the safety benefits of continuous monitoring approach in aviation. Ways for collecting and analysing FDM data are explored and possible methods for integrating the data with other data sources like occurrence reports are described. The analysis should also find answers to the following questions: How can normal operational data be used to monitor (trends) flight operations and flight crew behaviour?; and how can this information can be compared with expected operational and behavioural performance? Legal and organisational issues associated with the collection and use of flight data and other data sources are not considered in this section. The focus is on the technical possibilities and issues.

Ref:ASCOS_WP2_IoA_D2.3Page:45Issue:1.0Classification:Restricted

3.3.2 The Use of FDM today

Airline operators make use of commercially available FDM programme software to analyse and monitor flight data from normal operations. The FDM analysis typically comprises of two elements: analysis of event exceedances and analysis of routine events. Event exceedance analysis is the classical way of looking at flight data. It looks for deviations from defined limits, standard operating procedures and good airmanship. An example is a deviation from a target approach speed. Routine event analysis does not look at deviations. Instead it looks at the distribution of parameters recorded for each flight. An example is the recording and analysis of deviations from the target approach speed of each flight as shown in Figure 3.

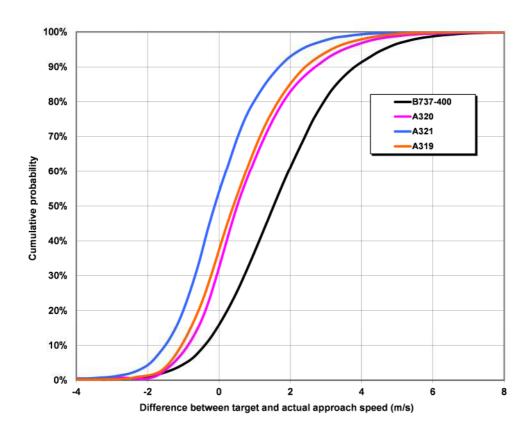

Figure 3 Example of routine event data (source: NLR)

Historically some regulators have been using flight data to support a range of airworthiness tasks. Examples are the recording and analysis of in-flight turbulence (gust loads), landing impact loads, characteristics of autopilot nuisance disconnects, autopilot-aircraft coupled oscillatory behaviour, manoeuvring acceleration profiles, encountered weather conditions etc. Most of these efforts were limited to a small group of operators or aircraft types. Airline operators also can use flight data for their own continued airworthiness purposes like autoland performance, engine thrust levels, system performance monitoring, flying control performance, brake and landing gear usage. Use of flight data for continued airworthiness is therefore not entirely new. However, the use of flight data at an European aggregation level has not been explored yet as well as

Ref:ASCOS_WP2_IoA_D2.3Page:46Issue:1.0Classification:Restricted

integrating it with other data sources like occurrence reports. Such an initiative is attempted in the United States with the FAA Aviation Safety Information Analysis and Sharing (ASIAS) System. The ASIAS system is an initiative by the government and industry to share and analyse safety data proactively and timely to identify safety issues and mitigation measures. It enables users to perform integrated queries across multiple databases, search an extensive warehouse of safety data, and display pertinent elements in an array of useful formats. Flight data are part of the data that are collected (called FOQA data in the US). A large number of US operators provide their flight data to the ASIAS system and as of mid-2012 44 airlines provide data from their voluntary occurrence reporting programs to the ASIAS system. The airline safety data are being safeguarded by The MITRE Corporation which also performance the data processing and analyses. The ASIAS system is currently not used for continued airworthiness purposes. Some examples of data analysis challenges of ASIAS are described in ref. [47]

3.3.3 Setting up a flight data database at a European aggregation level

There are basically two approaches of setting up flight data database at a European aggregation level. In the first approach operators provide predefined parameters or events from their FDM programme to the central database. In the second approach the operators simply provide all their raw flight data recordings (time traces) to the database. Both approaches are discussed in more detail.

3.3.4 Central collection of predefined FDM parameters/events

The first approach is the easiest one for the entity that collects stores and analyses the data. Values of the parameters are simply stored into a database including some background data like type of aircraft and date. This process is illustrated in Figure 4. Event exceedances can be collected in this way. Routine events can also be collected in this way. However, this will give a continuous flow of data from the airline operators to the entity as the parameters are recorded for each flight. Difficulties arise in this approach from the wide variation of parameter definitions that are being used by the operators. It is known that there are often no common definitions used for the many parameters that are collected through FDM. This is especially true for event exceedances. For instance the thresholds used to detect an exceedance can vary amongst the different operators. The pre-defined criteria for event exceedances typically exist of two components: predetermined thresholds of the parameter and the duration of exceedance of the parameter to trigger an event. These criteria are determined by reference to the various operational manuals and are often tailored to the individual requirements of the operator. This means in practice that different criteria can be used by the operators for monitoring the same event. For example an operator defines the flap placard speed exceedance as any speed that is higher than the flight manual placard speed for at least two seconds. Another operator has defined the flap placard speed exceedance as any speed that is 5 knots higher than the flight manual placard speed for at least three seconds. Although both operators look at the same event, they do not get the same results in terms frequency of occurrence of flap placard speed exceedances. Another example is for unstabilised approaches which are monitored by most operators. There are many different ways for defining an unstabilised approach. Although the standard operating procedures provided by operators to their flight crews are often very similar (even for different aircraft types), the way unstabilised approaches are identified

Ref:ASCOS_WP2_IoA_D2.3Page:47Issue:1.0Classification:Restricted

from the flight data is not. Different criteria and definitions are applied by operators to monitor unstabilised approaches. Also the various FDM software tools used by the operators can have use different internal definitions for the parameters they produce from the flight data. Controlling these issues have proven to be very difficult as operators are often reluctant to change their own in-house definitions, simply do not have the resources to build custom queries to extract common defined parameters, and/or are limited by the FDM software tools they use. Another major drawback of the first approach is that it is very inflexible when new safety issues emerge. One can only analyse those parameters that have been pre-defined and recorded. If new parameters need to be analysed, these have to be collected again from the operators. This collection process can take up significant time as historical flight data are often not available from the operators.

3.3.5 Central collection of raw flight data

In the second approach, the airlines provide raw flight data to a central database where the data is further processes and analysed by an entity to determine the aggregate FDM parameters/events. The second approach lacks the important drawbacks of the first approach. As raw data are collected in this approach, the entity that collects and analyses the data can use its own definitions and criteria for the parameters. These definitions and criteria apply automatically to all operators that provided raw time traces. Also the possibility to look for new parameters is much easier and faster in the second approach as historical records are kept of the raw flight data. The second approach is illustrated in Figure 5. Note that the second approach of raw flight data collection is also used in the FAA ASIAS system. A major drawback to the second approach is that all the collected raw flight data need to be stored, processed and analysed using special software tools. Also expert knowledge in flight data analysis and flight operations is required within the staff of the entity that is responsible for this process. The format in which the raw flight data are provided can also complicate the data processing. If raw data are provided in binary format (zeroes and ones) the conversion into meaningful engineering units (feet, knots) is done using a data map, a sort of conversion table. This data map is required for every airline's aircraft fleet as it is dependent on the on-board avionics systems and their set-up. The airline will have the data map as part of their FDM programme and this should be submitted to the collecting entity together with the raw flight data. If the airline operators submit processed data, or time traces of engineering units, they will do the processing of the raw data and the data map is not an issue. This all requires significant resources to manage (mainly cost of the software and man-hours) which will be much higher than for the first approach.

In both approaches de-identification of the flight data will be needed. Identification of flight crews should not be possible. However, identification of aircraft types is essential for using the flight data for continued airworthiness purposes.

Ref:ASCOS_WP2_IoA_D2.3Page:48Issue:1.0Classification:Restricted

Approach one

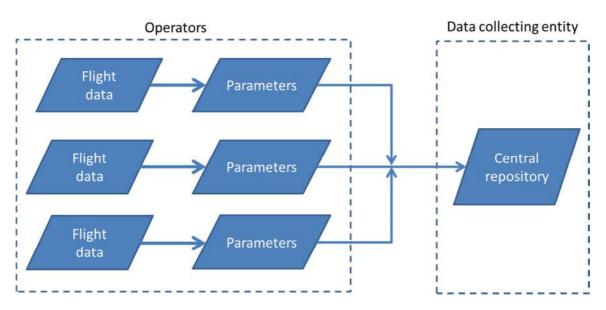

Figure 4 Illustration of approach one for flight data collection

Approach two

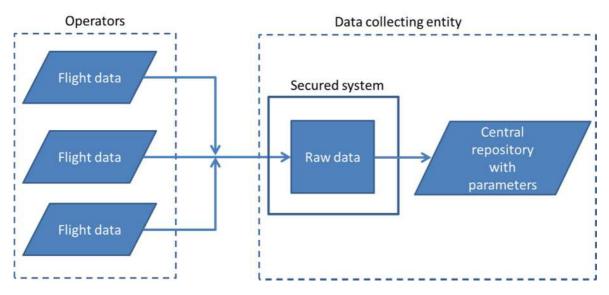

Figure 5 Illustration of approach two for flight data collection

3.3.6 Exposure data

When using the first approach for collecting flight data events /parameters, care should be taken to also collect corresponding exposure data like the number of flights and flight hours in order to be able to normalise

Ref:ASCOS_WP2_loA_D2.3Page:49Issue:1.0Classification:Restricted

the data. In the second approach raw flight data are collected which allows determination of the number of flights and flight hours. When collecting occurrence reports from airlines the collection of corresponding exposure data is essential as well.

3.3.7 Use of flight data for continuous safety monitoring

During certification many assumptions are made about the operational conditions, crew behaviour (e.g. response times), and system performance. Flight data provides an excellent source for monitoring (trends) in flight operations, system performance and flight crew behaviour which provides feedback on the assumptions made in certification and helps to identify new/changed hazards and assess associated risks. In most cases events can be defined in the FDM software to monitor flight data in areas that are directly related to for instance operational conditions, crew behaviour and system performance. The data for the events can be compared with the operational, system and behavioural performance as assumed during certification. Both event exceedances and routine events can be used for this purpose. Examples of event exceedances that can be monitored are stick shaker activation, high normal loads, Maximum Operating Mach Number Mmo, and low buffet margin events. Routine event examples are pilot reactions times to e.g. Terrain Awareness and Warning System TAWS alerts, aircraft system performance like erroneous radio altimeter signals or unreliable indicated airspeeds, and flight crew procedures non-compliance like engaging autopilot or autothrottle systems during approach and landing in the event of a radio altimeter malfunction.

In Figure 6 an example of the frequency distribution of the pilot reaction time to a TAWS alert is shown (based on more than 18 million flights). The distribution of response times shown can be compared to an assumed minimum pilot response time as defined in for instance EUROPEAN TECHNICAL STANDARD ORDERS ETSO-C151b for Terrain Awareness and Warning Systems.

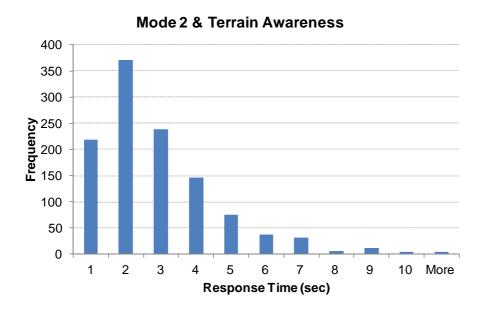

Figure 6 Example pilot reaction time distribution to TAWS alert (source: Honeywell)

Ref:ASCOS_WP2_IoA_D2.3Page:50Issue:1.0Classification:Restricted

Another example of flight data analysis in support of continuous safety monitoring is the data-mining exercise performed by the UK AAIB in the aftermath of the Boeing 777 fuel-icing related accident at Heathrow on 17 January 2008. Flight data from more than half a million flights were analysed during the investigation for various variables like fuel temperature in flight and engine fuel flow on long-duration B777 flights with the aim to detect any parameters or a combination of parameters that were unique to the accident flight.

When using the first approach for collecting flight data events, care should be taken to also collect corresponding exposure data like the number of flights and flight hours in order to be able to normalise the data. In the second approach raw flight data are collected which allows determination of the number of flights and flight hours.

3.3.8 Integration of flight data with other data sources

Benefits can be obtained when the recorded flight data events are linked with other data sources. Integration with other available data for improved contextual picture and in some cases it is essential for the analysis. For instance TAWS events could have occurred in day VMC conditions in which pilots do not always have to respond to the alerts per the Standard Operating Procedures. The general weather conditions are not recorded in the flight data and therefore it is recommended to link the data with archived weather reports. Linking flight data with other data sources like weather is already done by some operators.

Flight data events can also be linked with occurrence reports like air safety and maintenance reports. This is often done by individual operators. The advantage is that the reports by personnel will provide context to the exceedance/event detected in the FDM programme. From the FDM programme you may learn "what happened, and when", but not "why". The latter is relevant in the safety analysis and for mitigation. It should be realised that it is possible that no safety report has been submitted for an apparently reportable incident which is however detected by the FDM programme. Events that are not subject to mandatory occurrence reporting would normally not be reported by flight crews. In other cases the flight crew simply could have believed that the occurrence was only of low significance and no formal report was submitted by the crew. On the other hand, the crew may decide to submit a report as part of the airline's (voluntary) reporting program. These problems arise when trying to link an individual safety report to the corresponding flight data. For continuous safety monitoring it could be more interesting to validated trends found in e.g. occurrence data with flight data and vice versa. This however requires that the definitions used for an occurrence are the same as for the flight data events.

If the entity also collects occurrence data from the airline operators a few issues need to be taken into consideration. First, there is no standard for reporting forms, so records from (voluntary) reporting programs will differ across the airline industry. The level of detail, completeness and quality of the reports will vary, even within a single airline. Taxonomies used to classify occurrences and the risk levels of occurrences vary by airlines as well.

Ref:ASCOS_WP2_IoA_D2.3Page:51Issue:1.0Classification:Restricted

Secondly, the information in the records and narratives may contain very relevant safety information, but it takes a significant effort to analyse large sets of occurrence reports. The safety analyst has to go through the records individually to assess the information contained in the reports. It takes time and manpower to be able to select the reports relevant to the analysis at hand, and to make an assessment of the relation of the reports to FDM parameters/events. There is no substitute yet for "manual" review of records. Automatic techniques, like text—mining have not yet reached a maturity level to do the analysis and processing effectively and correctly.

De-identification of data is necessary, but as a drawback useful information may be lost for the analysis.

Some airlines are starting to employ techniques like bow-tie models to structure the integration of different data sources. The models are used for representation of the relation between hazards, safety barriers and undesired outcomes. They contain events which can be quantified or associated with FDM parameters (e.g. hard landing, unstable approach) and occurrence reports from voluntary reporting programs. This way the models provide a "hook" for data from FDM and occurrence reports to help the analyst to monitor and assess the quality of the safety barriers for example.

The entity that collects flight data and data from other sources may need to develop similar models as well to enable the integration of data from different sources to be able "to connect the dots" and to analyse the safety information from FDM and occurrence data for continued airworthiness purposes.

3.3.9 Integration of flight data with ECCAIRS

The ECCAIRS is not suited to do any kind of flight data processing nor can be used for the identification of event exceedances and routine events. Changing the ECCAIRS software to be able to do this is also not feasible. Specialised FDM software is needed for that purpose. However the event exceedances and routine events data obtained from the flight data can be stored into the ECCAIRS system together with the corresponding background data like aircraft type, weather etc. without major changes to the ECCAIRS software.

3.3.10 Final remarks

Flight data provide an excellent source to enhance the safety benefits of continuous monitoring approach in aviation. It is feasible to use flight data to monitor (trends) flight operations and flight crew behaviour and compare this information with expected operational and behavioural performance. The most flexible and effective approach is to collect raw time trace flight data, however this requires significant resources to manage.

Ref:ASCOS_WP2_loA_D2.3Page:52Issue:1.0Classification:Restricted

3.4 The Automatic Safety Data Gathering in ATM as a source for continuous safety monitoring

In analogy with FDM, the Automatic Safety Data Gathering (ASDG) may be defined as the process of using an automated system to detect occurrences that may be related to the safety performance of the ATM system, to collect and record relevant context data, and to assist with the interpretation of the occurrence data [36]. Since the late nineties, this process has been encouraged by EUROCONTROL with the design of the Automatic Safety Monitoring Tool (ASMT), a tool that supports the monitoring of safety performances at the level of the overall ATM Safety. The information obtained with this tool can help the Air Navigation Service Providers (ANSPs) to define improvement actions in the following domains:

- SMS efficiency
- Airspace / airways structure design & sector configuration
- Local procedures review
- Operational analysis of the impact of traffic distribution / Sector charge on safety
- Regulation / flow management
- Alert equipment and operational techniques

Originally developed in 1996 at the EUROCONTROL Experimental Centre, the ASMT has the capability to collect and analyse track data and flight plans in quasi-real time. Two different types of events trigger the ASMT recordings:

- Internal Events, i.e. events directly collected by the ASMT internal logic
- External Events, based on alerts received by ground and airborne safety nets.

The first category includes the following events.

- **Proximities**: infringements of separation minima between aircraft
- Altitude Deviations: detections of aircraft that do not comply with the cleared flight level (e.g. Level Bust)
- Airspace Penetrations: detection of unauthorised penetrations of a segregated airspace
- Rate of Closure: infringements of vertical and horizontal distances occurring with a 'rate of closure' exceeding a specified value.

While the second category includes the following events.

- Short Term Conflict Alerts: predicted infringements of separation minima, triggered by the reception of an STCA message series from the ATC system
- Area Proximity Warning: predicted infringements of a segregated airspace
- Airborne Collision Avoidance System Resolution Advisory: Traffic Collision Avoidance System (TCAS)
 resolution advisory following the detection of a threat from another aircraft (triggered by the
 reception, through the Mode-S downlink data, of an ACAS Resolution Advisory message generated by
 an aircraft Traffic).

Ref:ASCOS_WP2_IoA_D2.3Page:53Issue:1.0Classification:Restricted

For each detected occurrence, ASMT stores the relevant data (shortly before, during and shortly after the event) into a database that can be later queried to extract the data or to review the occurrence in a dedicated replay window. The recording of all these events correspond to different ASMT software modules, which can be configured independently at local level, focusing the priority on one or the other aspect, depending on the safety policies and SMS of the specific ANSP.

While most of the ANSPs are still relying on manual reporting, there are advantages of using a tool like ASMT. First of all the automatic monitoring can help to spot the occurrences that are not collected with the manual monitoring and to focus the attention also on minor safety occurrences with an operational relevance. Such occurrences may actually help to have a more accurate overview of the current level of safety (e.g. minor separation minima infringements or altitude deviations with no safety consequences). Secondly, the availability of a large amount of data opens new opportunities for a statistical characterization of the data set under analysis. In this case, compared to current investigation processes, the attention focus shifts from the causes and dynamics of single events to emerging statistical characteristics [49]. Examples of these statistical characteristics could be:

- **Identification of patterns** and **hotspots** (e.g. the areas with a higher concentration of a certain safety occurrence. Refer to Figure 7);
- **Trend analysis** (e.g. the daily, weekly or seasonal variations of the amount of a certain safety occurrence);
- **Correlation Analysis** (e.g. the link between the Flight Level at which the aircraft is flying and the *risk of collision* associated to a loss of separation occurrence).

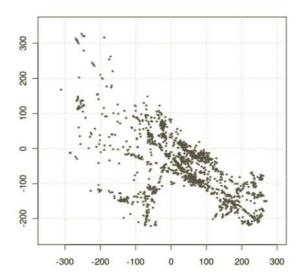

Figure 7 Example of STCA events plotted on an X-Y map to identify STCA hot spots (source: Pozzi et al. 2011)

The current major limitation of ASMT is certainly the sensitivity of the data being collected, especially as far as legal recording and human reporting are concerned. ASMT can be easily considered as a "big brother" tool, spying over the controller's shoulder and supporting a blame culture of punishment. Therefore, before starting

Ref:ASCOS_WP2_IoA_D2.3Page:54Issue:1.0Classification:Restricted

implementing ASMT in an organization, clear safety policies should be established to favour its acceptability, by clarifying the scope of the associated safety monitoring and by providing the necessary assurance that the tool is intended to improve safety at a system level and not to punish individual operators. After its initial introduction and testing in 1996 and after the following software developments since 2004 (when the ASMT project started to be managed by the EUROCONTROL HQ), such difficulties have partially slowed down the adoption of the tool around Europe. Nonetheless the ASMT is now installed in 6 European ANSPs and other ASDG tools with a similar purpose and logic were developed and installed independently in other 4 European ANSPs. [38]

3.4.1 Potential use of ASDG in the ASCOS Safety Performance Monitoring

Duly integrated with FDM and the voluntary reporting of the aviation system operators, the ASDG in ATM may offer an excellent opportunity to feed the Safety Monitoring Process envisaged by ASCOS. Despite the number of European ANSPs with an ASDG tools being installed is still limited and characterized by a heterogeneous configuration and use of the tool itself, the possibility to have automatically generated data of a significant part of relevant safety occurrences appears very promising. Major obstacles are of course the legal implications of the provision of safety data under the authority of each EU State and the lack of standardization in the definition of each safety occurrence. Nonetheless the Commission Implementing Regulation (EU) N. 390/2013 aimed at defining Key Performance Indicators (KPIs) for four Key Performance Areas (KPAs), including Safety, could be considered a first step to overcome these limitations [14]. As a matter of fact, such Implementing Regulation introduces the Risk Analysis Tool originally proposed by EUROCONTROL [39] as a mean to classify three categories of occurrences at the European Union Level: Separation Minima Infringements, Runway Incursions and ATM-specific Occurrences. Furthermore it includes, among others, the performance indicators "The application by the air navigation service providers of automated safety data recording systems where available, which shall include, as a minimum monitoring of separation minima infringements and runway incursions".

To further encourage this process, the approach which is here proposed is to distinguish the automatically generated data that should be retained at local level for the purposes of local safety policies, from the data that might be shared at European level in order to contribute to the Safety Monitoring Process of the Total Aviation System. If we refer for example to the wide range of recording modules of ASMT, it is clear that not all of them would produce information easily comparable at European level.

Data such as those triggered by the ground Safety Nets (e.g. the STCA and APW) might be very useful for improvement processes at local level. As documented in some recent case studies [50], when correlated with other ASMT data, they could help to validate the "fit-for-purposeness" of the STCA in a specific operational environment or to spot configuration issues of the Multi Radar Tracking system (MRT) in systematic manner. On the other hand they will have a limited comparability at a global level, especially since the safety nets and the MRT are generally implemented in a different way and with different configurations depending on the specific ANSP and Area Control Centre.

Ref:ASCOS_WP2_loA_D2.3Page:55Issue:1.0Classification:Restricted

Data such as the Infringements of Separation Minima or the Levels Busts – which have been indicated among the ASCOS SPIs - will be easily comparable, especially if they are classified with a common scheme such as the EUROCONTROL Risk Analysis Tool (RAT) [39]. As suggested in [43] this severity criterion may also be used to distinguish inside a specific occurrence category the vents to be shared at global level, from those that can be retained at local level for the ANSP's own safety policy applications.

For example, concerning the Infringements of Separation Minima, the RAT method calculates the risk of collision (ROC) as a combination of two different scores in a dedicated marksheet (refer to Figure 8): a score indicating the minimum separation achieved between two aircraft and a score indicating the rate of closure between the two aircraft.

1. Risk of collision	ATM ground	ATM airborne	ATM overal
Minimum separation achieved	0	0	
Separation + 75% minimum	1	1	
Separation >50%, <=75% minimum	3	3	
Separation >25%, <=50% minimum	7	7	
Separation <=25% minimum	10	10	2
Total separation (a)			
Rate of closure NONE	0	0	
Rate of closure LOW (<=85knots, <=1000ft/mn)	1	1	
Rate of closure MEDIUM (>85 and <=205 knots, >1000 and <=2000 ft/mn)	2	2	
Rate of closure HIGH (>205 and <=700 knots, >2000 and <=4000 ft/mn)	4	4	
Rate of closure VERY HIGH (>700knots, >4000ft/mn)	5	5	
Total rate of closure (b)			

Figure 8 Example of Severity Marksheet from the Risk Analysis Tool (EUROCONTROL 2009)

In this case it is proposed to select only the Infringement of Separation Minima with a ROC higher than 7. In the 'separation' part of the marksheet a score of 7 corresponds to a separation included between the 25% and the 50% of the applicable separation minima. With such a severe loss of separation, even the combination with a rate of closure of 1 (corresponding to a low rate of closure, included between 60 kts and 1000 ft per minute) would produce a ROC of 7 and lead to the inclusion of this occurrence among those to be monitored at global level. On the other hand, the same rate of closure will produce a ROC lower than 7, if combined with a less severe infringement of Separation Minima (e.g. more than the 75% of applicable separation minima) and would be considered only as a safety occurrence to be investigated at local level, after a qualitative consideration of its actual dangerousness.

Ref:ASCOS_WP2_IoA_D2.3Page:56Issue:1.0Classification:Restricted

3.5 Flight simulator data as input for continuous safety monitoring

The simulators provide a controlled environment for analysing influences on human performance. Studies involving flight simulators and air traffic control simulators are particularly relevant for pilot performance and air traffic controller performance.

US report on The Aviation System Monitoring and Modeling discovered the following aspects of proactive management of safety risk can be met only with simulation [57]:

- Determination of human and machine requirements for successful task performance (perceptual, cognitive, motor, and informational);
- Description of possible mechanisms for that performance;
- Definition of causal relationships between the human operators and the context, in which they
 operate;
- Prediction of performance of human-system model involving multiple interacting humans and machines under nominal operating environments;
- Identification of hazards and their causal factors in new operating environments for which there are no data or experience;
- Determination of risks of identified and unexpected hazards.

The following examples of simulation data analysis are mentioned in the research papers [56]:

- the balked landing and missed approach manoeuvres providing data for pilot control behaviour for different aircraft configurations and weather conditions (NASA Ames);
- human in the loop simulations to understand the factors that contribute to taxiway navigation errors (NASA Ames);
- human in the loop simulations with air traffic controllers and included measurements of controller workload (NASA Ames, NLR).

At organisational level, however, there are no facilities to study simulation data. Only expert judgment is available at this level. [56]

Assuming the human factor data generated during professional programs of simulated flights are as valid as real-flight data, the ASCOS SPIs of Human level automatically detected among this data may serve as safety performance evaluation of the diagnosed personnel (refer to Figure 9)

3.6 Protection of safety data

Information provided by aviation personnel is essential for safe operation of a complex and vulnerable air transport system. Potentially fatal accidents and incidents in the transport system operation can be prevented only when the underlying or contributing safety issues are known in time. Often the only source of an early warning of a safety issue or a deficiency is the personnel.

People are, most often, willing to share their knowledge if their personal safety and privacy is assured, that is their identities will remain protected and there are neither disciplinary nor legal consequences for reporting. In this safety-oriented approach, it is important to learn and fix mistakes rather than pursue possible offenders. Consequently, a properly constructed reporting system is confidential, voluntary, non-punitive, independent and can be used by any person to safely share information. Closed reporting systems have known weaknesses, as legal and financial responsibility may disrupt investigation, even if limited protection of reporters exists. But most importantly, unless incident data is shared with other systems, the safety information gathered by the closed system is lost to users throughout the industry [1].

Ref:ASCOS_WP2_loA_D2.3Page:58Issue:1.0Classification:Restricted

Given the potential for misuse of safety data that have been compiled strictly for the purpose of advancing aviation safety, database management must include protection of the data. Protection considerations include:

a) Adequacy of protection — access to information. Regulations vis-à-vis safety management requirements.

The only purpose of protecting safety information from inappropriate use is to ensure its continued flow from the aviation community, so that adequate preventive actions can be taken in time to improve aviation safety. Protection of safety information should not interfere with the proper administration of justice. National laws and regulations protecting safety information require a balance between the need of protection of safety information for improvement of aviation safety, and the need for proper administration of justice. Protection of qualified safety information, including provision of appropriate national regulations, is part of each state responsibilities. The protection measures, including necessary formal procedures, are suited specifically for each SDCPS, depending on the safety information stored [1].

b) Policies limiting information flows (need to know only).

Considering the sensitivity, in some states, regarding the dissemination of incident information, only accredited representatives and their advisers provide the state conducting the investigation with all relevant information available to them and may not divulge information on the progress and the findings of the investigation without the express consent of the State conducting the investigation.

The Authority will not disclose the name of the person submitting the report or of a person to whom it relates unless required to do so by law or unless, the person concerned authorizes such disclosure.

c) De-identification.

As the only purpose of incident information collection is the improvement of safety, including accident prevention, all reports need to be de-identified. De-identification is carried out by removing all the information enabling to track the original reporters: names of persons, places, registration numbers, etc.

After the reports are read, accepted and de-identified, or rejected the original problems reports need to be destructed to prevent their improper use.

d) Security of information systems.

The requirements for security of information systems are stipulated by national regulations in each country. Regulations protecting the right for privacy stipulate the need to protect personal data and levels of protection. The subject of protection is also sensitive data of organisations. Security requirements are also included in regulations regarding electronic commerce (which include data storage) and electronic data protection.

Ref:ASCOS_WP2_IoA_D2.3Page:59Issue:1.0Classification:Restricted

The aim of regulations is to secure confidentiality of data, prevention of unauthorized access, use, disclosure, disruption, destruction, modification, perusal, inspection, recording and to secure that the data processing standards are met.

The standards play a key role in evaluation of security level of information. These include standards published by ISO, IEC, TIA or ANSI (e.g. TIA/EIA 942A, EN 1047-2:2009, EN 50173-5, ISO/IEC 11801 2002, ISO/IEC 24764, ANSI/BICSI 002-2011, EN50600, ISO/IEC 27001:2013, BS 7799-2, ISO/IEC 27002:2005).

Security of the information systems is addressed in the security policy implemented in the organisation managing databases. The policy defines which data needs what defined level of protection and what authorisation is granted to which users. Security policy is enforced by the security mechanisms that include software protection in operational systems, databases, as well as physical protection. In databases, the control means include discretionary and mandatory access control, statistical databases are accessed by sum-queries and operations audits are performed. Other means of protection include RIAD matrices (also backup), data encryption, firewalls, digital certificates and encrypted connection (SSL).

e) Prohibitions on unauthorized use of data.

The analyses for the purpose of safety improvement can be carried out only based on aircraft incident information, without the need for identifying it as such. Therefore, before publication of the results all the data need to be de-identified. Names of persons, owners, operators, states of registry and registry/serial numbers may not appear in the public reports. Formal criteria are required for disclosure of any information, they may include the need to correct hazards to safety, improve policies or regulations. Any person or organisation willing to disclose the information should justify the release of information. The disclosure of any information must be done in a de-identified form to protect privacy and respect appropriate regulations and not inhibit further information flow from the aviation community [1].

3.7 Conclusions and recommendations on the safety data management

The quality and quantity of data collected is a fundamental requirement for safety data to be used effectively for continuous safety monitoring. The flow of safety data from operator level to regulatory authorities must become an integral part of safety management requirements and become established as such in the governing legislation.

To address data quality issues, requirements can be gradually introduced to establish a common taxonomy, data format, etc. at operator level. This will influence the manner data is collected and create greater standardisation with regards to taxonomy and compatibility of commercially available safety reporting/management software with that used by the central repository. This can become part of the framework for future safety reporting schemes and ensure seamless reporting across all stakeholders directly into the central database.

Ref:ASCOS_WP2_IoA_D2.3Page:60Issue:1.0Classification:Restricted

The same applies to the potential use of FDM in airlines and ASDG in ATM for continuous safety monitoring at a regulatory level. Achieving this will mean breaking away from many of the constraints which limit effective data sharing among the stakeholders of the aviation community. Data protection laws require that flight data is used in a de-identified manner whilst still generating safety benefit of using the data in aggregate format.

Flight data provide an excellent source to enhance the safety benefits of continuous monitoring approach in aviation. It is feasible to use flight data to monitor (trends) flight operations and flight crew behaviour and compare this information with expected operational and behavioural performance. The most flexible and effective approach is to collect raw time trace flight data. This will generate greater benefit and flexibility from a safety management perspective than a process which relies on reporting pre-defined safety parameters and events. The downside is that the collecting, processing and analysis of raw time traces requires significant resources.

Some flight data standardisation initiatives are beginning to emerge among European operators and the regulatory authorities, industry and EASA. The EASA led European Operators Flight Data Monitoring (EOFDM) forum and the UK CAA's FDM forum are two such initiatives which are not only enabling operators to implement FDM and get the most benefit out of such a system but are looking at novel ways of combining collective experience and limited de-identified datasets to better identify safety hazards through FDM.

Although there is still a long way to go until raw flight data is collected on a systematic basis, such European initiatives bring together key stakeholders and are a step in the right direction which may pave the way for future use of flight data for continuous safety monitoring.

The best way to get benefit from the opportunities offered by the ASDG in ATM seems the distinction between a specific set of safety occurrences to be shared at global level to feed the continuous safety monitoring and another set of data to be retained at local level in support of local safety policies. In the latter case data may be shared with the Regulatory authorities only in the usual form of a manual reporting, after appropriate qualitative investigation has taken place by the service provider. The criteria proposed to distinguish the two sets of data is the identification of the ATM safety occurrences selected among the ASCOS SPIs and the adoption of the EUROCONTROL RAT tool as a way to isolate the most severe occurrences.

Ref:ASCOS_WP2_loA_D2.3Page:61Issue:1.0Classification:Restricted

4 Safety performance monitoring process for system of organisations

The list of ASCOS SPIs includes a level for System of organisation indicators elaborated for the aggregate performance monitoring. In fact any other ASCOS SPIs could be aggregated to this level, however only System of organisation SPIs count hazards that originate from the interfaces between different organisations.[43]

The idea of ASCOS is to include the events of System of organisation SPIs within the existing occurrence reporting and within State Safety Programmes of the EASA Member States. It is assumed, that the collection of these SPIs, the same as any other ASCOS SPIs, would be done by the ECCAIRS database.

The same philosophy of the management of change (PDCA) described for Safety Assurance at a service provider level (concerning Technology, Human and Organisation SPIs) would apply to the use of System of organisation level SPIs. (refer to 2.1.3)

The main difference would concern the leading SPIs and the precursors that were linked to these SPIs (refer to Appendix D, SPIs 47-63). Apart from other qualities (e.g. their normalisation would be determined case by case), the leading SPIs are positioned in different location in the chain of events. The precursors linked to these SPIs are no longer "precursors", but the results. They are the effects of the events measured by the leading SPIs. The nomenclature, however, was not changed due to the metaprocess structure (refer to 2.2).

The SPIs no. 47-63, however, are the SPIs that go beyond the required extension to the EU regulations on the occurrence reporting [56] and were not recommended by the Section 6.4.1 of ASCOS D2.1 due to non-conformity to 6 criteria [43].

4.1 Atypicality scores for SPIs aggregates at System of organisations level

One of the descriptive statistics allowing identifying underperforming organisation is a function of the Mahalanobis distance. It measures a unitless distance from a common point (multivariate data centroid) taking into account the correlations of data set. The distance is calculated by the following matrix algebra formula:

$$D_M(X) = \sqrt{(X - \mu)' S^{-1}(X - \mu)}$$

Where:

X – n x k matrix of n SPIs aggregated per period in organisation k

 μ – n x 1 vector of e.g. means for SPIs

 $S - n \times n$ covariance matrix of the $(X - \mu)$ matrix

The atypicality distance values are found in the resulting $D_M(X)$ (diagonals of k x k matrix). Organisations with the highest atypicality distance (e.g. top 5%) are underperforming in terms of safety assurance and should be considered for further, detailed examination.

Ref:ASCOS_WP2_IoA_D2.3Page:62Issue:1.0Classification:Restricted

5 Conclusions and recommendations

5.1 Conclusions

- ASCOS method is aligned to the long-term ICAO Global Aviation Safety Plan (GASP) [7] to have appropriate performance indicators, to verify the causal factors and use the alert levels. The method supports the EASA recommended Management System (MS) and transition from quality management to SMS;
- ASCOS performance based safety monitoring process corresponds to the Continuous Monitoring Approach (CMA) used as integral part of the stakeholders' life cycle processes for the purpose of the Safety Assurance SMS component. The safety level is continuously monitored and semi-continuously measured;
- ASCOS method offers Safety Performance Indicators (SPIs) linked to causal factors precursors. An
 elaborated metaprocess allows for method improvement. A large number of occurrence reports will
 be required to obtain statistical confidence. The method is more oriented on precursors mitigation
 approach instead of traditional accident and incidents mitigation approach. It enables the prevention,
 mitigation or elimination of phenomena (precursors) directly leading to high risk events. When the
 TLS of the SPIs is exceeded, the list of identified precursors support root cause analyse and
 implementation of adequate risk mitigation plans;
- ASCOS SPIs can be counted using ECCAIRS taxonomy based occurrence reporting system;
- Flight data provides an excellent source for monitoring in flight operations, system performance and flight crew behaviour. FDM provides feedback on the assumptions made in certification and helps to identify new/changed hazards and assess associated risks;
- Bow-tie models contain events which can be quantified or associated with FDM parameters and occurrence reports from voluntary reporting programs;
- ATM related ASCOS SPIs (such as separation infringements, level busts) are easily comparable
 especially if they are classified with a common scheme such as the EUROCONTROL Risk Analysis Tool
 (RAT).

5.2 Recommendations

- ASCOS suggests the use of ASCOS SPIs method by service providers in their SMS Safety Assurance, in
 the process for safety performance monitoring and management. Due to the high number of possible
 consequences of a typical precursor, it is necessary to quantify the linkage between occurrence
 probability and chance for a given precursor to have occurred. It can be achieved by focussing more
 on the identified precursors when developing occurrence scenarios;
- It is proposed that the SPIs are collected using the ECCAIRS database and aggregated at the service provider level, state level and EU level. Wherever applicable, it is recommended to stay aligned to the ADREP taxonomy. Inclusion of the best practices, already used by EU local CAAs, mentioned by EASp is advised;
- Some minor additions to the taxonomy could be suggested to the ECCAIRS Taxonomy Working Group;

Ref:ASCOS_WP2_loA_D2.3Page:63Issue:1.0Classification:Restricted

- Data verification tools would be needed;
- Samples of classifications for various occurrence scenarios should be prepared that clarify the required event type sequences for standard occurrence scenarios;
- Linking the collected data with archived weather reports would be needed (already done by some operators).

Two approaches to FDM as the source for the SPIs are recommended:

- 1. **Central collection of predefined FDM parameters/events** allowing a continuous flow of data from the airline operators to the entity with a need to collect corresponding exposure data to normalise the data
- 2. **Central collection of raw flight data** allowing easy data collection (already used e.g. in the US FAA ASIAS system), but requiring special software tools to store, process and analyse

No matter what approach is chosen for continued airworthiness purposes, it is recommended to address data quality issues, requirements including a common taxonomy and data format, etc. at operator level as well as the potential use of FDM in airlines and ASDG in ATM for continuous safety monitoring at a regulatory level including de-identification of the flight data, but identification of aircraft types.

Appendix A The result: links between precursors and SPIs

Please refer to Appendix A.pdf for the full table of results (154 pages)

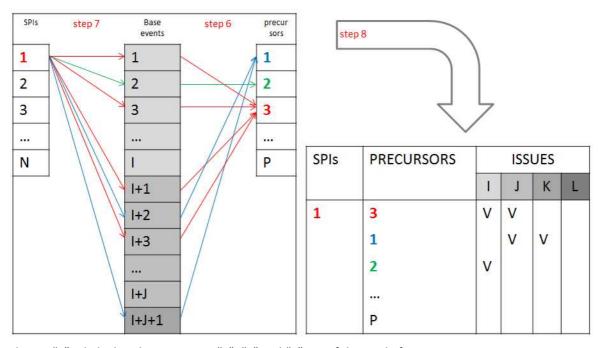

Brief explanation below, only.

The resulting set P_{SPI} of precursors corresponding to each of the SPIs was developed by a reduction of redundant information from the original Step 8 table. It was generated by the application of a conditional sum of sets on all precursors throughout all of the CATS for ASCOS v0.1 ESD Base Events. The condition was defined as a link to the same SPI of the same precursor. If this link was repeated several times the resulting set reports it only once.

$$P_{SPI} = \bigcup_{i \in Base\ Events} P_i \{p | SPI\}$$

where the set P_{SPI} is reported in Appednix A. pdf

and where any precursor $p \in P_i$

The SPI "1" is linked to the precursors "3", "1" and "2" out of the total of P precursors.

Ref:ASCOS_WP2_loA_D2.3Page:68Issue:1.0Classification:Restricted

An example. A quick scan of the Appendix B locates the same precursors at least 3 times for SPI1.

Appendix A, page 2, first line (example of the result of Step 8):

Wildlife incursion	5		V				
Adverse weather / poor visibility conditions / darkness	6		V				
Taxiway confusion	7		V	V			
Emergency landing	8		V	V			
Taxiway incursion	9		V	V			
Stand confusion	10		V	V			
inadequate anti-ice fluid holdover Time (HOT)	11		V	•			
Contaminated wing	12		V	V			
Continued unstabilized approach (failure to comply with go-around criteria and policy)	13			V			
AOA prevents missed approach	14		V	V			
System failures that may affect braking devices (ground spoilers, brakes / autobrake, thrust reversers)	15	V	V	V	V		
Gross loading error	16			V			
Cargo loading unsecured / shift	17			V			
Convective weather encounter	18		V	V			
Extreme turbulence encounter	19		V	V			
Extreme icing conditions encounter	20		V	V			
Windshear encounter	21		V	٧			
Volcanic ash encounter	22		V	V			
Mountain wave / vortices encounter	23		V	٧			
Wake turbulence encounter	24		V	V			
System failure affecting aircraft configuration, controllability and/or flying qualities	25	V			V		
System failure affecting the operation of primary instruments / displays or standby instruments	26	V			V		
Failures resulting in a non-standard fuel distribution	27	V			V		
Uncommanded thrust asymmetry	28	V			V		

Ref:ASCOS_WP2_loA_D2.3Page:70Issue:1.0Classification:Restricted

In-flight smoke / fumes / fire (in cockpit, cabin, cargo) events that could affect the crew ability to conduct their duties and/or the aircraft controllability	29	V		V	V
Extreme icing condition and / or heavy snow. Break in airport operation due to adverse weather or / and necessity of RWY surface maintenance.	31		V	V	
Convective weather / turbulence / windshear or crosswind conditions during take-off	32		٧	V	
Cabin pressure drop as a result of aircraft structural failure	33	V			V
Bird strike	34	-	V	V	-
Turbulence encounter	35		V	V	
Convective weather - heavy rain / hail resulted with engine compressor failure	36	V	-	-	V
Inadequate fuel quality / type	37			V	
Crew is incapable in result of extreme turbulence	38		V	V	
Contaminated Runway	39		V	V	
			V	V	.,
Engine suffers severe surge	40	V			V
Severe failure of all engines on transoceanic route or over rarely populated area	41	V	V		V
Severe engine failure	42	V			V
Missed approach execution necessary after prolonged flight due to e. g. extreme weather	44		V		
Adverse weather in terms of heavy rain or icing conditions resulted with decreased RWY surface friction rate	45			V	
Cautions / warnings (genuine or spurious) that may lead to a low-speed or high-speed rejected take-off	46		V		
Hard landing	47			V	
Rejected takeoff (whether initiated below or above 100 kt) (+) due to an					
aircraft system failure including engine	48	V			V
Severe structural failure of aircraft or / and its critical systems resulted from design load exceeding during touchdown	49	V		V	
GPWS / TAWS alert / warning (genuine or spurious)	50	V			V
MSAW warning	51	V			V
Other cases of reduced terrain separation	52	•		V	•
Prolonged loss of communications (PLOC) between pilot and controller(s)	53		V	V	
Low-energy state during approach	54	V	V	V	V
Land short (runway undershoot) event	55	V	V	V	V
Low altitude pattern following a go-around	56		V	V	
<u> </u>	57		V	V	
Inappropriate low altitude maneuvering					
Low-on-fuel condition / fuel starvation	58 59			V V	
Crew incapacitation resulted from illness (e.g. food poisoning)					
Natural or artificial obstacle on runway course	60			V	
Error in preparation of database for FMS	61				V
Ground Navigational Aid failure	62		V		V
Landing gear retraction failure	63	V			V
Frontal surface encounter	64		V	V	
Convective weather / turbulence / windshear encounter conditions during landing	65		V	V	
Midair collision	66		V	V	
Collision with ground obstacle	67		V	V	
Inadequate NOTAM information concerning ground navigational aid failure	68		V	V	
Inadequate navigational chart	69		V	V	
TCAS RA events (genuine or spurious)	70	V			V
Airspace infringement	71	-	V	V	-
Other cases of loss of separation	72		V	V	

Ref:ASCOS_WP2_loA_D2.3Page:71Issue:1.0Classification:Restricted

Prolonged loss of communication (PLOC) between pilot and controller	73		V	V	
Failures affecting TCAS operation	74	V			V
Convective weather - heavy rain resulted with wet RWY surface	75			V	
Convective weather encounter in traffic intensive airport proximity	76		V		
Engine failure	77	V			V
System failure affecting the operation of primary instruments / displays or standby instruments - ADS-B System	78	V			V
Cabin pressure drop as a result of pneumatic system failure	79	V			V
Tire burst	80	V			V
Risk of dangerous occurences appeared during take-off roll	85		V	V	
Line-up events	93	V	V	V	V
Aircraft swerve / lateral excursion during takeoff roll	96			٧	
Other cockpit effects / malfunctions (genuine or spurious) occurring during takeoff roll	98	V			V
Runway incursion	99		V	V	
Crew is incapable in result of shock related to hard landing	103				
Tailwind or crosswind landing with tailwind and/or crosswind					
component(s) in excess of applicable limit(s), either intentionally or unknowingly	116		V	V	
Bounced landing	118			V	
Deep (long) landing	119			V	
Temporary loss of directional control during rollout	120			V	
Lack of adherence to SOP for take-off procedure in terms of maintaining adequate separation on the RWY.	123			V	
Flaws in manufacturer quality control process - taxiing related control system (e.g. Brake failure)	124				٧
Lack of adherence to SOP for GND movements in terms of marshalling procedure	125			V	
Lack of adherence to SOP for GND movements in terms of flight crew - ground crew comunication.	126			V	
Lack of adherence to SOP for GND movements in terms of clearance providing by the controller.	127			V	
Flaws in ground equipment maintenance process	128		V		
Vehicle driver / equipment operator / ground agent tiredness - Inadequate workload distribution	129			V	
Flaws in vehicle driver / equipment operator / ground agent requirements definition process and/or training methodology	130			V

Appendix C.2 Precursors – deviations and their stakeholders

PRECURSORS			STAKEHOLDERS maintenance of certificates			
Deviations (Procedural/Flight Path)	No.	cont. airworthiness of aircraft	ANS	operators	manufacturers	
Inadvertent deviation from cleared taxi route	131			V		
Lack of English proficiency	132			V		
Incorrect or confusing / misleading ATC instructions	133		V			
Use of non-standard phraseology by pilot and/or controller	134		V	V		
Lack of adherence to emergency procedures - RWY collision avoidance	135			V		
Flaws in aircraft system maintenance process definition - stickshaker	136	V				
Traffic controller tiredness - Inadequate workload distribution	137		V			
Lack of adherence to SOP for GND movements. Poor execution of parking / docking /pushback procedure	138			٧		
Inefficient / confusing TWR traffic control procedures, inefficient management of hot spots	139		V			
Lack of adherence to SOP for GND movements. Lack of awareness of other traffic movements through listening of ATC communications	140			V		
Lack of adherence to SOP for GND movements.	141		V	V		
Lack of adherence to SOP for GND movements. Lack of awareness of	141		V	V		
own position on the airsite and airport topology.	142			V		
Lack of adherence to SOP for GND movements. Lack of awareness in terms of sufficient separation / clearence	143			٧		
Lack of adherence to SOP for GND movements. Lack of awareness in terms of current situation on the airsite or / and aircraft / vehicle proximity	144			V		
Flaws in traffic controller requirements definition process and/or training methodology	145		V			
Lack of or poor communication quality	146		V	V		
Lack of adherence to ICAO Annex 14 and related documents in terms of airside lights distribution	147		V	V		
Lack of adherence to SOP in terms of communication between ATC and pilot / vehicle driver	148		V	V		
Flaws in maintenance technician / airworthiness specialist requirements definition process and/or training methodology	149			V		
Maintenance technician / airworthiness specialist tiredness - Inadequate workload distribution	150			V		
Lack of adherence to the SOP in terms of PNF flight parameters / situation monitoring or / and passive contribution to the PF duties	151			V		
Inadequate stall recovery procedure for the aircraft	152				V	
Inadequate management / separation of takeoffs and landings	153		V		•	
Callsign confusion	154		V	V		
Current airport diagram not reflecting critical changes	155		*	V		
Lack of adherence to SOP in terms of awareness on supporting systems						
(warning) - RIMCAS.	156			V		
Takeoff without clearance	157			V		
Landing without clearance	158			V		
Inadequate de-icing method applied	159			V

Appendix D Safety Performance Indicators

List of Safety Po	erfor	mance Indicators	DIRECTIVE 2003/42/EC OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 13 June 2003 on occurrence reporting in civil aviation
Technology	1	Rate of autoflight	Appendix to ANNEX I
		system failures/flight	2. Autoflight system
			(a) failure of the autoflight system to achieve the intended operation while engaged
			(b) significant reported crew difficulty to control the aircraft linked to autoflight system functioning
			(c) failure of any autoflight system disconnect device
			(d) uncommanded autoflight mode change.
Technology	2	Rate of electrical	Appendix to ANNEX I
		power system	4. Electrical system
		failures/flight	(a) loss of one electrical distribution system (AC/DC)
			(b) total loss or loss of more than one electrical generation system
			(c) failure of the back up (emergency) electrical generation system.
Technology	3	Rate of flight control	Appendix to ANNEX I
		system failures/flight	7. Flight controls
			(a) asymmetry of flaps, slats, spoilers, etc.
			(b) limitation of movement, stiffness or poor or delayed response in the operation of primary flight control systems
			or their associated tab and lock systems
			(c) flight control surface runaway
		(d) flight control surface vibration felt by the crew	
			(e) mechanical flight control disconnection or failure
			(f) significant interference with normal control of the aircraft or degradation of flying qualities.
Technology	4	Rate of fuel system	ANNEX I
	failures/flight	A. AIRCRAFT FLIGHT OPERATIONS	
			(i) Operation of the aircraft
			(q) Fuel system malfunctions or defects, which had an effect on fuel supply and/or distribution.
			Appendix to ANNEX I
			8. Fuel system
			(a) fuel quantity indicating system malfunction resulting in total loss or wrong indication of fuel quantity on board
			(b) leakage of fuel which resulted in major loss, fire hazard, significant contamination

Ref:ASCOS_WP2_loA_D2.3Page:86Issue:1.0Classification:Restricted

List of Safety Performance Indicators			DIRECTIVE 2003/42/EC OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 13 June 2003 on occurrence reporting in civil aviation
			(c) malfunction or defects of the fuel jettisoning system which resulted in inadvertent loss of significant quantity,
			fire hazard, hazardous contamination of aircraft equipment or inability to jettison fuel
			(d) fuel system malfunctions or defects which had a significant effect on fuel supply and/or distribution
			(e) inability to transfer or use total quantity of usable fuel.
Technology	5	Rate of hydraulic	ANNEX I
		power system	A. AIRCRAFT FLIGHT OPERATIONS
		failure/flight	(i) Operation of the aircraft
			(u) Inability to achieve the intended aircraft configuration for any flight phase (e.g. landing gear and gear doors,
			flaps, stabilisers, slats etc.).
			(k) Leakage of hydraulic fluids, fuel, oil or other fluids which resulted in a fire hazard or possible hazardous
			Appendix to ANNEX I
			9. Hydraulics
			(a) loss of one hydraulic system (ETOPS only)
			(b) failure of the isolation system
			(c) loss of more than one hydraulic circuit
			(d) failure of the back-up hydraulic system
			(e) inadvertent ram air turbine extension.
Technology	6	Rate of ice/rain	Appendix to ANNEX I
		protection system failures/flight	10. Ice detection/protection system
			(a) undetected loss or reduced performance of the anti-ice/de-ice system
			(b) loss of more than one of the probe-heating systems
			(c) inability to obtain symmetrical wing de-icing
			(d) abnormal ice accumulation leading to significant effects on performance or handling qualities
			(e) crew vision significantly affected.
Technology	7	Rate of landing gear system failures/flight	ANNEX I
		System ramures/mgmt	A. AIRCRAFT FLIGHT OPERATIONS
			(i) Operation of the aircraft
			(u) Inability to achieve the intended aircraft configuration for any flight phase (e.g. landing gear and gear doors,
			flaps, stabilisers, slats etc.).
			(x) Operation of any primary warning system associated with manoeuvring the aircraft e.g. configuration

Ref:ASCOS_WP2_loA_D2.3Page:87Issue:1.0Classification:Restricted

List of Safety Performance Indicators			DIRECTIVE 2003/42/EC OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 13 June 2003 on occurrence reporting in civil aviation
Technology	8	Rate of navigation system failures/flight	warning, stall warning (stick shaker), over-speed warning etc. unless: 3. the warning results from failure to select landing gear or landing flaps by the appropriate point on the approach (mode 4); or 12. Landing gear system/brakes/tyres (a) brake fire (b) significant loss of braking action (c) asymmetrical braking action leading to significant path deviation (d) failure of the landing gear free fall extension system (including during scheduled tests) (e) unwanted landing gear or gear doors extension/retraction (f) multiple tyre burst. ANNEX I A. AIRCRAFT FLIGHT OPERATIONS (i) Operation of the aircraft (o) Incorrect programming of, or erroneous entries into, equipment used for navigation or performance calculations, or use of incorrect data. D. AIR NAVIGATION SERVICES, FACILITIES AND GROUND SERVICES (i) Air navigation services (ANS) 13. Navigation systems (including precision approach systems) and air data systems (a) total loss or multiple navigation equipment failures (b) total or multiple air data system equipment failures (c) significant misleading indications (d) significant navigation errors attributed to incorrect data or a database
			(e) unexpected deviations in lateral or vertical path not caused by pilot input (f) problems with ground navigational facilities leading to significant navigation errors not associated with
Technology	9	Rate of powerplant system failures/flight	transitions from inertial navigation mode to radio navigation mode. ANNEX I A. AIRCRAFT FLIGHT OPERATIONS (iii) Propulsion (including engines, propellers and rotor systems) and auxiliary power units (APUs)
			(a) Flameout, shutdown or malfunction of any engine.

Ref:ASCOS_WP2_loA_D2.3Page:88Issue:1.0Classification:Restricted

(b) Overspeed or inability to control the speed of any high-speed rotat component (for example: APU, air starter, air cycle machine, air turbine motor, propeller or rotor). (c) Failure or malfunction of any part of an engine or powerplant resul in any one or more of the following: 1. non-containment of components/debris; 2. uncontrolled internal or external fire, or hot gas breakout; 3. thrust in a direction different from that demanded by the pilot; 4. thrust-reversing system failing to operate or operating inadvertently 5. inability to control power, thrust or rpm; 6. failure of the engine mount structure; 7. partial or complete loss of a major part of the powerplant; 8. dense visible fumes or concentrations of toxic products sufficient to incapacitate crew or passengers; 9. inability, by use of normal procedures, to shutdown an engine; 10. inability to restart a serviceable engine. (d) An uncommanded thrust/power loss, change or oscillation which is classified as a loss of thrust or power control (LOTC): 1. for a single-engine aircraft; or 2. where it is considered excessive for the application; or where this could affect more than one engine in a multi-engine aircraft particularly in the case of a twin-engine aircraft; or	List of Safety Performan	DIRECTIVE 2003/42/EC OF THE EUROPEAN PARLIAMENT A THE COUNCIL of 13 June 2003 on occurrence reporting in civil aviation	AND OF

			(j) Failure or malfunction of any part of a propeller or powerplant resulting in any one or more of the
			following:
			1. an overspeed of the propeller;
			2. the development of excessive drag;
			3. a thrust in the opposite direction to that commanded by the pilot;
			4. a release of the propeller or any major portion of the propeller;
			5. a failure that results in excessive imbalance;
			6. the unintended movement of the propeller blades below the established minimum in-flight low-pitch
			position;
			7. an inability to feather the propeller;
			8. an inability to change propeller pitch;
			9. an uncommanded change in pitch;
			10. an uncontrollable torque or speed fluctuation;
			11. the release of low-energy parts.
			Rotors and transmission
			(k) Damage or defect of main rotor gearbox/attachment which could lead to in-flight separation of the rotor
			assembly and/or malfunctions of the rotor control.
			(I) Damage to tail rotor, transmission and equivalent systems.
			APUs
			(m) Shut down or failure when the APU is required to be available by operational requirements, e.g. ETOPS,
			MEL.
			(n) Inability to shut down the APU.
			(o) Overspeed.
			(p) Inability to start the APU when needed for operational reasons.

Appendix E ICAO USOAP Program and Continuous Monitoring Approach and EASA Standardisation

Appendix E.1 ICAO USOAP Program and Continuous Monitoring
Approach

ICAO USOAP Program and CMA overview

USOAP CMA background

The ICAO Universal Safety Oversight Audit Programme (USOAP) was launched on 1 January 1999, pursuant to a resolution A32-11, which was adopted at the 32nd Session of the ICAO Assembly, in response to widespread concerns about the adequacy of aviation safety oversight around the world.

In recognition of the success achieved by USOAP, the 33rd Session of the Assembly (22 September – 5 October 2001) adopted Assembly Resolution A33-8, which expanded the USOAP to audits of Annex 11 — Air Traffic Services, Annex 14 — Aerodromes, and other safety-related areas such as Annex 13 — Aircraft Accident and Incident Investigation.

In September 2007, the 36th Session of the Assembly adopted Resolution A36-4 directing the Council to examine different options for the continuation of the USOAP beyond 2010, including the feasibility of applying a new approach based on the concept of continuous monitoring.

Pursuant to this resolution, the Council directed the Secretariat to look at the future of the programme beyond 2010, with a view to incorporating the analysis of safety risk factors, adopting a more proactive approach, making a more effective and efficient use of ICAO resources, and increasing the role of other ICAO bureaux and the regional offices (ROs). To this effect, in July 2008 the Secretariat established a study group to examine the feasibility of adopting a CMA. Based on a comparative analysis of the benefits, constraints and implementation costs, the study group resolved that, in order to ensure efficiency, long-term sustainability and cost-effectiveness, preference should be given to the application of a CMA for the continuation of USOAP beyond 2010.

The 37th Session of the Assembly (September – October 2010) adopted Resolution A37-5, affirming that the evolution of USOAP to the CMA should be a top priority for ICAO to ensure that information on the safety performance of Member States is provided to other Member States and to the travelling public on an ongoing basis.

Critical elements of a safety oversight system

ICAO specifies eight critical elements of the safety oversight system that cover the entire area of operations in civil aviation [4,5]. The level of effective implementation of the critical elements is an indication of a State's capability for safety oversight. These are:

1. **Primary aviation legislation** (aviation law consistent with the environment and complexity of the State's aviation activity and compliant with the requirements contained in the Convention on International Civil Aviation).

Ref:ASCOS_WP2_IoA_D2.3Page:102Issue:1.0Classification:Restricted

- Specific operating regulations (adequate regulations providing for standardized operational procedures, equipment and infrastructures (including safety management and training systems), in conformance with the Standards and Recommended Practices (SARPs) contained in the Annexes to the Convention on International Civil Aviation).
- 3. **State civil aviation system and safety oversight functions** (Civil Aviation Authority (CAA), supported by the appropriate and adequate technical and non-technical staff and provided with adequate financial resources).
- 4. **Technical personnel qualifications and training** (minimum knowledge and experience requirements for the technical personnel performing safety oversight functions and the provision of appropriate training).
- 5. **Technical guidance, tools and provision of safety-critical information** (technical guidance (including processes and procedures), tools (including facilities and equipment) and safety-critical information, to the technical personnel to enable them to perform their safety oversight functions in accordance with established requirements and in a standardized manner).
- 6. Licensing, certification, authorization and/or approval obligations (processes and procedures to ensure that personnel and organizations performing an aviation activity meet the established requirements before they are allowed to exercise the privileges of a licence, certificate, authorization and/or approval to conduct the relevant aviation activity).
- 7. **Surveillance obligations** (processes, such as inspections and audits, to proactively ensure that aviation licence, certificate, authorization and/or approval holders continue to meet the established requirements and function at the level of competency and safety).
- 8. **Resolution of safety concerns** (processes and procedures to resolve identified deficiencies impacting aviation safety, which may have been residing in the aviation system and have been detected by the regulatory authority).

Audit areas

The following eight audit areas have been identified in the USOAP:

- 1) primary aviation legislation and civil aviation regulations;
- 2) civil aviation organization;
- 3) personnel licensing and training;
- 4) aircraft operations;
- 5) airworthiness of aircraft;
- 6) aircraft accident and incident investigation;
- 7) air navigation services; and
- 8) aerodromes and ground aids.

The Continuous Monitoring Approach (CMA) concept

The objective of USOAP CMA is:

to promote global aviation safety through continuous monitoring of the Member States' safety oversight capabilities.

The USOAP CMA provides a mechanism for ICAO to collect safety information from Member States and other stakeholders and to analyse this information using a risk-based approach to identify and prioritize appropriate activities to be carried out by ICAO.

USOAP CMA is designed to monitor the safety oversight capabilities and safety performance of States on a continuous basis.

Ref:ASCOS_WP2_IoA_D2.3Page:103Issue:1.0Classification:Restricted

The CMA online framework provides ICAO. Member States and other authorized users with a suite of web-integrated applications that allow continuous monitoring and reporting of safety-related information and documentation received from different sources.

The Online Framework consists of the following:

- State Aviation Activity Questionnaires (SAAQs);
- Compliance Checklists (CCs);
- Protocol Questions (PQs);
- Mandatory Information Requests (MIRs);
- Findings and Recommendations (F&Rs);
- Significant Safety Concerns (SSCs);
- Corrective Action Plans (CAPs).

The following cycle describes the processes of collecting and analysing data under the CMA, and how this information is then used to prioritise strategies. The CMA captures vast amounts of data from ICAO member States and other stakeholders. The cycle consists of four major components [5]:

- a) collection of safety information;
- b) determination of State safety risk profile;
- c) prioritization and conduct of USOAP CMA activities; and
- d) update of the Lack of Effective Implementation (LEI) and the status of Significant Safety Concerns (SSCs).

The first component is the process of gathering information about safety.

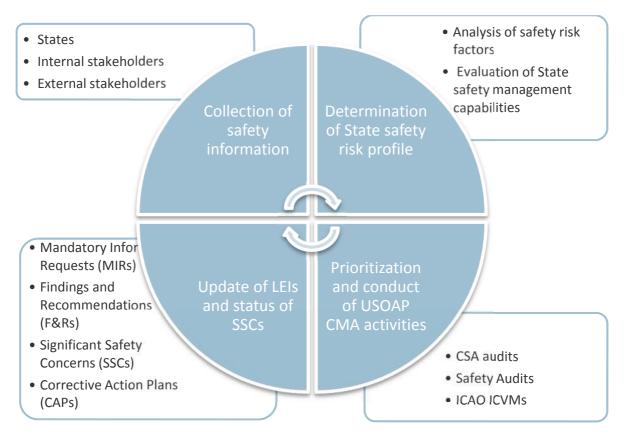

The information comes from three sources: Member States, internal and external stakeholders. Member States provide the primary source of safety information by completing, submitting and updating State Aviation Activity Questionnaire (SAAQ), Compliance Checklists (CCs - through the EFOD system) and USOAP CMA Protocol Questions (PQs).

Internal stakeholders (ICAO Secretariat, bureaux, sections and offices) provide information to the USOAP CMA that are collected and shared internally through ICAO's Integrated Safety Trend Analysis and Reporting System (ISTARS).

The third source of information is confidential safety information based on agreements with external stakeholders including national, regional, supranational and international organizations recognized by ICAO.

Ref:ASCOS_WP2_loA_D2.3Page:104Issue:1.0Classification:Restricted

The USOAP CMA components

The second component is the process of determination of State safety risk profile.

The State safety risk profile is based on various safety risk indicators that identify or highlight specific information related to a State that needs to be considered in identifying and prioritizing USOAP CMA activities.

These safety risk indicators include: Lack of Effective Implementation (LEI), Significant Safety Concern (SSC), the level of aviation activities in the State related to each audited area, the projected growth of aviation activities in the State, the level of acceptability of the State's Corrective Action Plan (CAP) and its implementation progress and progress in implementing a Safety management system (SMS) and State safety programme (SSP). The State safety risk profile is monitored on an ongoing basis at ICAO Headquarters.

Where the CMA process indicates that a State is not making progress in resolving identified Findings and Recommendations (F&Rs) and/or SSCs, or if the collected information indicates that the safety oversight system in a State has deteriorated, ICAO may take actions such as: increase the monitoring of the State, provide or facilitate assistance, consider financial or technical aid, reassess or monitor more closely existing technical assistance projects.

Next component is the process of prioritization and conduct of USOAP CMA activities

This process covers activities conducted by ICAO Monitoring and Oversight Section (CMO) and ICAO Regional office (ICAO ROs) to identify deficiencies in a State and to assess and elaborate Finding and Recommendation (F&Rs) and Significant

Ref:ASCOS_WP2_IoA_D2.3Page:105Issue:1.0Classification:Restricted

Safety Concerns (SSCs). These are: Comprehensive Systems Approach (CSA) Audits, Safety Audits and ICAO Coordinated Validation Missions (ICVMs).

The objective of a CSA Audit is to determine a State's capability for safety oversight by assessing the effective implementation of the eight CEs of the safety oversight system and the status of the State's implementation of all safety-related ICAO SARPs, associated procedures, guidance material and best safety practices. The objective of a Safety Audit is to an audit of its current safety oversight system.

The objective of an ICVM is to assess and validate the status of corrective actions or mitigating measures taken by a State to address previously identified F&Rs, including SSCs. ICVMs also include on-site guidance provided to the State in resolving remaining deficiencies.

The final component is the process of update of Lack of Effective Implementations (LEIs) and status of Significant Safety Concerns (SSCs).

Estimation of collected safety information enables ICAO to continuously update the Lack of Effective Implementation (LEI) of the safety oversight capability for each State. The LEI is based on the number of applicable non-satisfactory Protocol Questions (PQs). The LEI for each State may be updated based on the information received through Mandatory Information Requests (MIRs) and Corrective Action Plans (CAPs) indicating progress made in resolving Findings and Recommendations (F&Rs) and Significant Safety Concerns (SSCs).

If an F&R is considered to be an immediate safety risk to international civil aviation, the State will be informed of the identification of an SSC and requested to take immediate mitigating or corrective actions. If appropriate evidence is not provided by the State that such actions have been taken within a specified timeframe, all Member States will be notified of the SSC through the CMA online framework.

State obligations under the USOAP CMA

Member States shall sign USOAP CMA Memorandum of Understanding (MOU) with ICAO to confirm their full support of the USOAP CMA process and to commit to actively participating in all USOAP CMA activities, including the provision of information through the CMA online framework. Member States should secure adequate resources to meet all the conditions of the MoU.

Each State is responsible for identifying one or more qualified National Continuous Monitoring Coordinators (NCMCs) to act, on an on-going basis, as primary point(s) of contact for all USOAP CMA processes and activities.

The NCMC is responsible for maintaining and updating the information to be provided by the State to the CMO Section on an on-going basis, including:

- SAAQ,
- CCs,
- State responses to PQs,
- State responses to MIRs,

Ref:ASCOS_WP2_loA_D2.3Page:106Issue:1.0Classification:Restricted

- CAPs to resolve F&Rs,
- Mitigating measures taken by the State in response to SSCs,
- The latest information regarding the SSP, and
- Other relevant safety information, as requested by ICAO.

The NCMC shall coordinate the completion and ongoing update of the CCs in order to provide the CMO with information regarding the implementation of provisions of the relevant Annexes to the Convention.

Perspectives of the use of USOAP CMA

The effective SSP implementation is one of the near-term ICAO Global Aviation Safety Plan (GASP) [7] objectives. It is a gradual process requiring time, depending on complexity of air transportation and applicable to States with mature safety oversight systems. Since 14 November 2013 the overarching safety management provisions of the Annexes have been transferred into a new **Annex 19**[2]. It is supported by guidance of Safety Management Manual (Doc 9859) which 3rd edition of 2013 was substantially enhanced. The four components of the SSP were elevated to the status of ICAO Standard to match the SMS framework. The SSP implementation timeline was organised into four phases [6]:

- Phase 1 (12 months) identification of SSP place holder, executives, establishing SSP teams, perform gap analysis, develop implementation plan, establish coordination mechanism, develop documentation.
- Phase 2 (12 months) establish a legislative framework, document safety management responsibilities, define
 State safety policy and objectives, establish accident investigation process, basic enforcement, provide for safety oversight, promote SMS education.
- Phase 3 (24 months) promulgate enforcement policy, develop harmonised legislation requiring SMS, establish safety data collection and exchange system, establish State SPIs and target levels.
- Phase 4 (24 months) review and agree upon service provider's SPIs, incorporate SMS and SPIs into routine surveillance programme, implement voluntary/confidential safety reporting, establish lower consequence indicators, promote safety information exchange among organisations across ICAO, prioritise inspections based on the analysis of safety risk, establish internal review mechanism

Starting May 14th, 2014, ICAO is going to monitor Member States' implementation of SSP through the Universal Safety Oversight Audit Programme (USOAP) [2]. The necessary input is supposed to be acquired through the adjusted USOAP State Aviation Activity Questionnaire (SAAQ) grouped in alignment with phased-approach implementation and Protocol Questionnaires (PQs) as appropriate [10].

The Memorandum of Cooperation between EU and ICAO of 2010 [14] provided a framework for enhanced cooperation including coordination of respective audits and inspection programmes avoiding duplication of efforts.

The implementation of the USOAP CMA provides ICAO effective system of continuous monitoring and management in the field of civil aviation. The system allows carrying out both corrective actions and improvement actions.

Ref:ASCOS_WP2_loA_D2.3Page:107Issue:1.0Classification:Restricted

Appendix E.2 EASA Standardisation

Legal bases of EASA standardisation

In accordance with the will of Member States of the European Community and having regard to the Treaty establishing the European Community, in July 2002, the European Parliament and the Council of the European Union introduced Regulation (EC) No 1592/2002 on common rules in the field of civil aviation and establishing a European Aviation Safety Agency, called Basic Regulation. In this way, the process of creating the common law was launched. Further regulations expand the scope of the common law and EASA competences (see Table 1).

Table 1: The process of extending the scope of the common rules and EASA competences

Regulation	Competences
Regulation (EC) No 1592/2002	Initial Basic Regulation: 1. Initial and continuing airworthiness 2. Environmental compatibility
Regulation (EC) No 216/2008 [24]	Basic Regulation: (repealing Council Directive 91/670/EEC, Regulation (EC) No 1592/2002 and Directive 2004/36/EC) First extension: 1. Flight Crew Licencing (FCL) 2. Operation of Aircraft (OPS) 3. Safety of foreign operators
Regulation (EC) No 1108/2009 [51]	Second extension: 1. Air Traffic Management (ATM) 2. Air Navigations Services (ANS) 3. Aerodromes

The principal objective of this Regulation [24] is **to establish and maintain a high uniform level of civil aviation safety in Europe**. There are also six additional objectives of this Regulation:

- a) to ensure a high uniform level of environmental protection;
- b) to facilitate the free movement of goods, persons and services;
- c) to promote cost-efficiency in the regulatory and certification processes and to avoid duplication at national and European level;
- d) to assist Member States in fulfilling their obligations under the Chicago Convention, by providing a
 basis for a common interpretation and uniform implementation of its provisions, and by ensuring that
 its provisions are duly taken into account in this Regulation and in the rules drawn up for its
 implementation;
- e) to promote Community views regarding civil aviation safety standards and rules throughout the world by establishing appropriate cooperation with third countries and international organisations;
- f) to provide a level playing field for all actors in the internal aviation market.

Ref:ASCOS_WP2_IoA_D2.3Page:108Issue:1.0Classification:Restricted

To achieve these objectives, the European Union took the following means:

- 1) the preparation, adoption and uniform application of all necessary acts;
- 2) the recognition, without additional requirements, of certificates, licences, approvals or other documents granted to products, personnel and organisations in accordance with the Regulation and its implementing rules;
- 3) the establishment of an independent European Aviation Safety Agency (EASA);
- 4) the uniform implementation of all necessary acts by the national aviation authorities and the Agency within their respective areas of responsibility.

Article 10 of the Basic Regulation [24] specifies the requirements in the area of oversight and enforcement. The Member States, the Commission and EASA cooperate with a view to ensuring that any product, person or organisation subject to the Basic Regulation complies with its provisions and with its implementing rules.

Member States, in addition to their oversight of certificates that they have issued, conduct investigations, including ramp inspections, and take any measure, including the grounding of aircraft, to prevent the continuation of an infringement.

EASA conduct investigations in accordance with Article 24 and Article 55. The tasks of EASA include:

- Standardisation inspections, in order to monitor the application by national competent authorities of the Basic Regulation and of its implementing rules, and report to the Commission;
- Investigations of undertakings to monitor the application of the Basic Regulation and its implementing. All necessary investigations of undertakings EASA may conduct itself or assign to national aviation authorities or qualified entities. These investigations are carried out in compliance with the legal provisions of the Member States in which they are to be undertaken.
- Assessment of the impact of the implementation of the Basic Regulation and its implementing rules, having regard to its objectives.

The working methods of EASA for conducting the above tasks lay down implementing rules. Table 2 contains a list of implementing rules.

Table 2: List of Implementing rules in area of the oversight and enforcement the Basic Regulation

Implementing Regulation	Subject
Commission Regulation (EC) No 736/2006	Working methods of the European Aviation Safety Agency for conducting standardisation inspections
Commission Regulation (EC) No 859/2008	Safety of third-country aircraft using Community airports
Commission Directive 2008/49/EC	Criteria for the conduct of ramp inspections on aircraft using Community airports
Commission Regulation (EU) No 691/2010	Performance scheme for air navigation services and network functions, common requirements for the provision of air navigation services
Commission Regulation (EU) No 805/2011	Detailed rules for air traffic controllers' licences and certain certificates
Commission Implementing Regulation (EU) No 1034/2011	Administrative procedures for the safety oversight of air traffic management and air navigation services

Ref:ASCOS_WP2_IoA_D2.3Page:109Issue:1.0Classification:Restricted

Implementing Regulation	Subject
Commission Implementing Regulation (EU) No 1035/2011	Common requirements for the provision of air navigation services
Commission Regulation (EU) No 1178/2011	Technical requirements and administrative procedures related to civil aviation aircrew
Commission Implementing Regulation (EU) No 90/2012	Amending Regulation (EC) No 736/2006 on working methods of the European Aviation Safety Agency for conducting standardisation inspections
Commission Implementing Regulation (EU) No 923/2012	Common rules of the air and operational provisions regarding services and procedures in air navigation
Commission Regulation (EU) No 965/2012	Technical requirements and administrative procedures related to air operations
Commission Implementing Regulation (EU) No 628/2013	Working methods of the European Aviation Safety Agency for conducting standardisation inspections and for monitoring the application of the rules of Regulation (EC) No 216/2008 of the European Parliament (repealing Commission Regulation (EC) No 736/2006)

Process of standardisation

Process of standardisation is a process monitoring the application by competent authorities of the Member States of common rules in the field of civil aviation. Standardisation does not include the rulemaking process, but standardisation is directly associated with the rulemaking process. The legal basis for this activity stems from Art. 24(1) of the Basic Regulation.

The EASA Approvals and Standardisation Directorate [52] is responsible for ensuring that the EU aviation safety legislation is properly, uniformly and consistently applied Articles 24 (Monitoring the application of the rules), 54 (Inspections of Member States) and 55 (Investigation of undertakings) of the Basic Regulation. This role covers the inspections for standardisation of the National Aviation Authorities (NAAs).

In addition, inspections to NAAs are also performed by the Directorate in the context of the accreditation process for allocation of certification tasks.

The Standardisation department monitors the application by competent authorities of the requirements set in Basic Regulation and its Implementing Rules, as well as their uniform implementation. Such monitoring activity is continuous and risk-based, on the basis of the information available to the Agency.

It entails assessing the competent authorities' ability to discharge their safety oversight responsibilities, conducting inspections as necessary, as well as the follow-up of findings stemming from inspections, in order to ensure that appropriate corrections and corrective actions are timely implemented.

The organizational structure of the Standardization Department is shown in Figure below.

Ref:ASCOS_WP2_IoA_D2.3Page:110Issue:1.0Classification:Restricted

Organisation chart of EASA Standardisation Department

The primary objectives for EASA Standardisation Department [52] are to:

- Monitor the application of the rules by competent authorities (CAs);
- Conduct standardisation inspections of CAs;
- Contribute to the assessment of the impact of the implementation by CAs of Basic Regulation and its implementing rules;
- Perform international standardisation activities in line with Bilateral Aviation Safety Agreements or Working Arrangements;
- Ensure effective communication with CAs and facilitate exchange of data;
- Provide technical expertise assistance to the European Commission;
- Contribute to the certification and approval activities of the Agency by performing accreditation audits required by the MB Decision 01/2011 (Adopting the guidelines for the allocation of certification tasks to National Aviation Authorities and Qualified Entities), to both CAs and QEs.

In accordance with the provisions of Art. 24(5) of the Basic Regulation, the working methods of EASA for monitoring the application of the rules and conducting standardisation inspections are defined in Commission Implementing Regulation (EU) No 628/2013 [15].

Member States designate a National Standardisation Coordinator, acting as their primary point of contact for all standardisation activities and in particular to coordinate the exchange of information provided. The National Standardisation Coordinator is responsible for:

Ref:ASCOS_WP2_IoA_D2.3Page:111Issue:1.0Classification:Restricted

 Maintaining and updating the information provided to EASA on an on-going basis, corrections and corrective action plans and evidence of implementation of the agreed corrective actions

 Assisting EASA at all stages of an inspection and ensuring that the inspection team is accompanied throughout the on-site inspections.

This regulation introduces a fundamental shift from simple "inspecting" to full "monitoring", as EASA now puts in place a continuous and risk-based monitoring system.

This system (also called Continuous Monitoring Approach or CMA) is a cyclical approach that entails 5 components:

1. Collect information from Member States' Competent Authorities, ICAO, the EC and other sources

Competent authorities of Member States provide EASA with all necessary information relevant to their safety oversight, addressing all the critical elements of their safety oversight system, including the undertakings or associations of undertakings under their oversight.

The information are provided in a form and a manner specified by the Agency, taking into account the information that has been made available to ICAO. In general web-based interfaces are used.

EASA may also request ad-hoc information from the competent authorities of Member States. A National Standardization Coordinator is responsible for the provision of information to EASA from the Member States.

2. Analyse the Authorities' ability to discharge their safety oversight responsibilities

For the assessment EASA establishes, develops and maintains a single model taking into account at least the following elements:

- a) The size and complexity of the aviation industry;
- b) Serious incidents, accidents, fatal accidents and related fatalities;
- c) The results of ramp inspections;
- d) The results of previous inspections;
- e) The ability of the competent authorities to implement effectively corrections and corrective actions;
- f) The result of audits carried out under international conventions or State safety assessment programmes;

Ref:ASCOS_WP2_IoA_D2.3Page:112Issue:1.0Classification:Restricted

The collection and analysis of data and information provided by Member States, ICAO, the **Commission or other relevant** sources. The follow-up and closure of The assessment of the findings of non-conformity competent authority's ability stemming from the to discharge its safety inspections. oversight responsibilities. The conduct of such The prioritisation, planning and determination of the inspections, including the scope of inspections. related reporting.

Continuous monitoring process

The outcome of the model and the input data and results of the assessment are made available to the national standardisation coordinator of the Member State concerned.

3. Prioritise/plan/define the scope of inspections accordingly

EASA adapts the inspection programme in the light of its continuous monitoring, reflecting both improvements and deteriorations in safety performance. EASA takes appropriate action when there is evidence that the safety performance deteriorates.

EASA carries out inspections addressing each domain defined in Basic Regulation: airworthiness and environmental protection, air crew, air operations, ramp inspections, aerodromes, ATM/ANS and air traffic controllers.

4. Perform inspections where appropriate, when appropriate, as in-depth as appropriate

EASA performs three types of inspection:

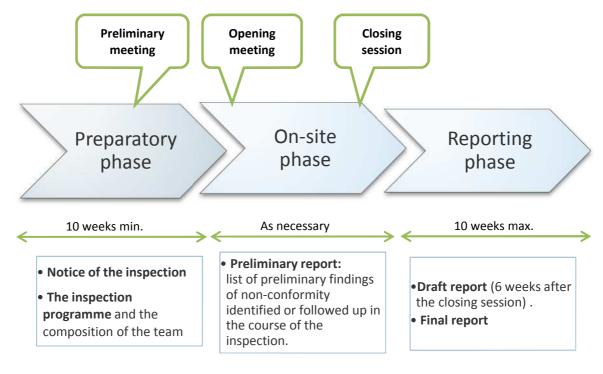

- a) Comprehensive inspections, for the purpose of inspecting one or more domains (regular, periodic);
- b) Focused inspections, for the purpose of inspecting specific areas within one or more domains, and/or for the purpose of assessing the implementation status of agreed corrections and corrective actions;
- c) Ad hoc inspections, for the purpose of investigating specific concerns arising from continuous monitoring or upon request from the Commission.

Ref:ASCOS_WP2_loA_D2.3Page:113Issue:1.0Classification:Restricted

Notwithstanding the inspections, EASA may identify off-site findings when it has collected sufficient evidence of non-conformity.

Inspections are carried out by teams set up by EASA. Each team has a team leader and one team member as a minimum. In all cases, EASA ensures the size of the teams remains commensurate to the scope.

EASA Inspection process

Comprehensive and focused inspections consist of the following phases:

- a) A preparatory phase, lasting a minimum of 10 weeks prior to the inspection.
 - During the preparatory phase, EASA gives notice of the inspection to the competent authority, including the intended type, domain(s) and areas for inspection.
 - Then it collects the necessary information (in particular from continuous monitoring) for the preparation of the inspection, define the scope, the extent and the programme of the inspection, including the inspection of undertakings or association of undertakings.
 - EASA determines the size and the composition of the inspection team.
 - EASA presents the inspection programme and the composition of the team to the competent authority at least 2 weeks before the on-site phase.
- b) An on-site phase.
 - During the on-site phase of an inspection, EASA organises an opening meeting with the National Standardisation Coordinator and the competent authority inspected.

Ref:ASCOS_WP2_loA_D2.3Page:114Issue:1.0Classification:Restricted

- Then, during the on-site inspection, the inspection team inspects the main offices, regional offices of the competent authority and undertakings or associations of undertakings under the oversight of the competent authority as part of the inspection of this competent authority.
- The inspection team carries out interviews with the staff and examines legislation, procedures, certificates, records, data and any other relevant material.
- At a closing session, the inspection team presents to the competent authority inspected a list of preliminary findings of non-conformity identified or followed up in the course of the inspection.
- c) A reporting phase, lasting a maximum of 10 weeks following the end of the on-site phase.
 - During the reporting phase of an inspection, EASA reviews the preliminary findings of nonconformity identified or followed up during the inspection, classifies them and establishes on this
 basis a draft report addressed to the competent authority inspected (within 6 weeks after the
 closing session of the on-site phase).
 - EASA issues a final report on the basis of the draft report (within 10 weeks after the closing session), reflecting the comments of the competent authority inspected, if any.
 - EASA may adapt the description of the finding of non-conformity, its legal basis, its classification
 or its status as appropriate to take into account the comments as well as the corrections or
 corrective actions submitted during the reporting phase.

5. Follow-up and closure of any finding stemming from the inspections.

All findings of non-conformity identified by EASA, in the framework of the inspections are classified and reported by EASA, whether they pertain to administrative requirements or to technical requirements, in one of the following classes:

- a) Class C: non-conformity with the applicable requirements, raising mainly standardisation concerns;
- b) Class D: non-conformity with the applicable requirements, raising standardisation concerns and safety concerns if not timely corrected;
- c) Class G: immediate safety concern.

When an immediate safety concern has been notified by EASA, EASA requests the competent authority to take adequate corrective actions, including immediate corrections. The competent authority applies effective corrections to remove the finding and provides EASA with evidence thereof.

When the corrections do not satisfy EASA, EASA makes recommendations to the Commission, including where necessary a request with regard to the mutual recognition of the certificate(s) issued by the competent authority. EASA also informs the competent authorities of the Member States immediately.

For all findings of non-conformity classified as Class D and G, the competent authority shall propose a correction and a corrective action no later than four weeks after receipt of the notification from EASA, for the findings of non-conformity classified as Class C - no later than 10 weeks after receipt of the notification from EASA. The competent authority also reports to EASA on the completion of corrective actions and provides evidence thereof.

Ref:ASCOS_WP2_IoA_D2.3Page:115Issue:1.0Classification:Restricted

EASA evaluates the corrections and the corrective actions submitted by the competent authority, agrees with or rejects the corrections and/or corrective actions, monitors the satisfactory implementation of corrective actions and closes the findings of non-conformity once satisfied with the completion of the corrective actions and the evidence provided, records the closure of the findings of non-conformity and informs the competent authority accordingly.

EASA has to perform standardisation inspections in all EU Member States, on the basis of the provisions of the Basic Regulation, as well as in Iceland, Liechtenstein, Norway and Switzerland, on the basis of bilateral or multilateral agreements signed between the EU and such States, which inter alia transpose the provisions of the Basic Regulation and its IRs.

Furthermore, EASA is entitled to perform standardisation inspections in several other countries based on specific Working Arrangements (WA) between EASA and the respective State.

In addition to inspections, the EASA Standardisation Department also:

- Performs ad-hoc and follow-up inspections where required;
- Raises off-site findings when it has collected sufficient evidence of non-conformity;
- Organises Standardisation meetings, workshops and webinars with CA's;
- Manages a web-based communication forum exchanging information with CA's (SINAPSE) and a webbased data collection tool (SIS) to receive and analyse relevant data;
- Participates in ICAO Universal Safety Oversight Audit Programme (USOAP) audits;
- Conducts Accreditation audits where CA's and Qualified Entities perform certain oversight tasks on behalf of the Agency;
- Provides technical experts to European Commission missions;
- Establishes the Agency's annual report on standardisation activities and regular reporting to the European Commission.

Coordination of ICAO USOAP CMA and EASA Standardisation

The ICAO USOAP CMA, described in Section 4, and EASA Standardisation, described in this section, have a similar approach to process safety monitoring. Both approaches assume the process of continuous monitoring and the monitoring based on safety performance. However, the transition from the monitoring compliance with rules to the continuous monitoring based on safety performance is a complex process.

A step in the right direction is the signing of Memorandum of Cooperation [53] between the European Union and the International Civil Aviation Organization providing a framework for enhanced cooperation which took place on 27 September 2010 during the course of the 37th Assembly of the International Civil Aviation Organization in Montréal. This Memorandum establishes cooperation between EU and ICAO in the areas: aviation safety, aviation security, air traffic management and environmental protection. The scope of cooperation in the area of aviation safety is specified in Annex 1 to the memorandum.

Overall scope of the cooperation covers:

Ref:ASCOS_WP2_loA_D2.3Page:116Issue:1.0Classification:Restricted

- conducting regular dialogue on safety matters of mutual interest,
- achieving transparency through the regular exchange of safety-relevant information and data and by providing mutual access to databases,
- participating in safety activities,
- mutually recognising the results of ICAO Universal Safety Oversight Audit Programme (USOAP) and EU Standardisation Inspections,
- monitoring and analysing States' compliance with ICAO Standards and adherence to Recommended Practices,
- cooperating in regulatory and standard-setting matters,
- developing and providing technical assistance projects and programmes,
- promoting regional cooperation,
- exchanging experts, and
- · providing training.

In the area of coordination of the ICAO USOAP and EU Standardisation Inspections, the Memorandum sets out:

- 1) The EU and ICAO agree to enhance their cooperation in the areas of USOAP and standardisation inspections in order to ensure effective use of limited resources and avoid a duplication of efforts, while preserving the universality and integrity of ICAO's USOAP.
- 2) In order to verify compliance by EU Member States with ICAO safety-related Standards and adherence to ICAO Recommended Practices, the EU and ICAO establish a framework for conducting, as appropriate:
 - a) ICAO safety oversight audits of EASA regarding safety-related SARPs that are addressed in EU legislation and with regard to certain functions and tasks which EASA performs on behalf of EU Member States; and
 - b) ICAO oversight of the EU Standardisation Inspections conducted by EASA of the national competent authorities of EU Member States regarding safety-related SARPs that are addressed by EU legislation.
- 3) The EU and ICAO establish working arrangements specifying the mechanisms and procedures necessary for the effective implementation of the framework referred to in point 2). These working arrangements shall address, inter alia, the following aspects:
 - a) the scope of ICAO USOAP intervention activities including audits and validation missions based on a comparative analysis of EU legislation and ICAO safety-related SARPs;
 - b) mutual participation in each Party's respective audit, inspection and validation activities;
 - c) information to be provided by each Party for the purposes of ICAO USOAP, and EASA Standardisation Inspections;
 - d) ensuring confidentiality where necessary, protection of data, and handling of sensitive information; and
 - e) on-site visits.

Ref:ASCOS_WP2_IoA_D2.3Page:117Issue:1.0Classification:Restricted

ICAO USOAP Program and CMA overview

USOAP CMA background

The ICAO Universal Safety Oversight Audit Programme (USOAP) was launched on 1 January 1999, pursuant to a resolution A32-11, which was adopted at the 32nd Session of the ICAO Assembly, in response to widespread concerns about the adequacy of aviation safety oversight around the world.

In recognition of the success achieved by USOAP, the 33rd Session of the Assembly (22 September – 5 October 2001) adopted Assembly Resolution A33-8, which expanded the USOAP to audits of Annex 11 — Air Traffic Services, Annex 14 — Aerodromes, and other safety-related areas such as Annex 13 — Aircraft Accident and Incident Investigation.

In September 2007, the 36th Session of the Assembly adopted Resolution A36-4 directing the Council to examine different options for the continuation of the USOAP beyond 2010, including the feasibility of applying a new approach based on the concept of continuous monitoring.

Pursuant to this resolution, the Council directed the Secretariat to look at the future of the programme beyond 2010, with a view to incorporating the analysis of safety risk factors, adopting a more proactive approach, making a more effective and efficient use of ICAO resources, and increasing the role of other ICAO bureaux and the regional offices (ROs). To this effect, in July 2008 the Secretariat established a study group to examine the feasibility of adopting a CMA. Based on a comparative analysis of the benefits, constraints and implementation costs, the study group resolved that, in order to ensure efficiency, long-term sustainability and cost-effectiveness, preference should be given to the application of a CMA for the continuation of USOAP beyond 2010.

The 37th Session of the Assembly (September – October 2010) adopted Resolution A37-5, affirming that the evolution of USOAP to the CMA should be a top priority for ICAO to ensure that information on the safety performance of Member States is provided to other Member States and to the travelling public on an ongoing basis.

Critical elements of a safety oversight system

ICAO specifies eight critical elements of the safety oversight system that cover the entire area of operations in civil aviation [4,5]. The level of effective implementation of the critical elements is an indication of a State's capability for safety oversight. These are:

- 9. **Primary aviation legislation** (aviation law consistent with the environment and complexity of the State's aviation activity and compliant with the requirements contained in the Convention on International Civil Aviation).
- 10. **Specific operating regulations** (adequate regulations providing for standardized operational procedures, equipment and infrastructures (including safety management and training systems), in conformance with the Standards and Recommended Practices (SARPs) contained in the Annexes to the Convention on International Civil Aviation).
- 11. **State civil aviation system and safety oversight functions** (Civil Aviation Authority (CAA), supported by the appropriate and adequate technical and non-technical staff and provided with adequate financial resources).
- 12. **Technical personnel qualifications and training** (minimum knowledge and experience requirements for the technical personnel performing safety oversight functions and the provision of appropriate training).
- 13. **Technical guidance, tools and provision of safety-critical information** (technical guidance (including processes and procedures), tools (including facilities and equipment) and safety-critical information, to the technical

Ref:ASCOS_WP2_loA_D2.3Page:118Issue:1.0Classification:Restricted

personnel to enable them to perform their safety oversight functions in accordance with established requirements and in a standardized manner).

- 14. Licensing, certification, authorization and/or approval obligations (processes and procedures to ensure that personnel and organizations performing an aviation activity meet the established requirements before they are allowed to exercise the privileges of a licence, certificate, authorization and/or approval to conduct the relevant aviation activity).
- 15. **Surveillance obligations** (processes, such as inspections and audits, to proactively ensure that aviation licence, certificate, authorization and/or approval holders continue to meet the established requirements and function at the level of competency and safety).
- 16. **Resolution of safety concerns** (processes and procedures to resolve identified deficiencies impacting aviation safety, which may have been residing in the aviation system and have been detected by the regulatory authority).

Audit areas

The following eight audit areas have been identified in the USOAP:

- 9) primary aviation legislation and civil aviation regulations;
- 10) civil aviation organization;
- 11) personnel licensing and training;
- 12) aircraft operations;
- 13) airworthiness of aircraft;
- 14) aircraft accident and incident investigation;
- 15) air navigation services; and
- 16) aerodromes and ground aids.

The Continuous Monitoring Approach (CMA) concept

The objective of USOAP CMA is:

to promote global aviation safety through continuous monitoring of the Member States' safety oversight capabilities.

The USOAP CMA provides a mechanism for ICAO to collect safety information from Member States and other stakeholders and to analyse this information using a risk-based approach to identify and prioritize appropriate activities to be carried out by ICAO.

USOAP CMA is designed to monitor the safety oversight capabilities and safety performance of States on a continuous basis.

The CMA online framework provides ICAO. Member States and other authorized users with a suite of web-integrated applications that allow continuous monitoring and reporting of safety-related information and documentation received from different sources.

The Online Framework consists of the following:

- State Aviation Activity Questionnaires (SAAQs);
- Compliance Checklists (CCs);
- Protocol Questions (PQs);
- Mandatory Information Requests (MIRs);

Ref:ASCOS_WP2_loA_D2.3Page:119Issue:1.0Classification:Restricted

- Findings and Recommendations (F&Rs);
- Significant Safety Concerns (SSCs);
- Corrective Action Plans (CAPs).

The following cycle describes the processes of collecting and analysing data under the CMA, and how this information is then used to prioritise strategies. The CMA captures vast amounts of data from ICAO member States and other stakeholders. The cycle consists of four major components [5]:

- e) collection of safety information;
- f) determination of State safety risk profile;
- g) prioritization and conduct of USOAP CMA activities; and
- h) update of the Lack of Effective Implementation (LEI) and the status of Significant Safety Concerns (SSCs).

The first component is the process of gathering information about safety.

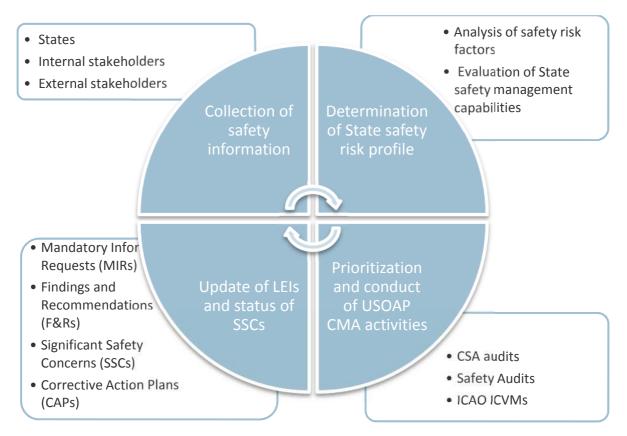

The information comes from three sources: Member States, internal and external stakeholders. Member States provide the primary source of safety information by completing, submitting and updating State Aviation Activity Questionnaire (SAAQ), Compliance Checklists (CCs - through the EFOD system) and USOAP CMA Protocol Questions (PQs).

Internal stakeholders (ICAO Secretariat, bureaux, sections and offices) provide information to the USOAP CMA that are collected and shared internally through ICAO's Integrated Safety Trend Analysis and Reporting System (ISTARS).

The third source of information is confidential safety information based on agreements with external stakeholders including national, regional, supranational and international organizations recognized by ICAO.

Ref:ASCOS_WP2_loA_D2.3Page:120Issue:1.0Classification:Restricted

The USOAP CMA components

The second component is the process of determination of State safety risk profile.

The State safety risk profile is based on various safety risk indicators that identify or highlight specific information related to a State that needs to be considered in identifying and prioritizing USOAP CMA activities.

These safety risk indicators include: Lack of Effective Implementation (LEI), Significant Safety Concern (SSC), the level of aviation activities in the State related to each audited area, the projected growth of aviation activities in the State, the level of acceptability of the State's Corrective Action Plan (CAP) and its implementation progress and progress in implementing a Safety management system (SMS) and State safety programme (SSP). The State safety risk profile is monitored on an ongoing basis at ICAO Headquarters.

Where the CMA process indicates that a State is not making progress in resolving identified Findings and Recommendations (F&Rs) and/or SSCs, or if the collected information indicates that the safety oversight system in a State has deteriorated, ICAO may take actions such as: increase the monitoring of the State, provide or facilitate assistance, consider financial or technical aid, reassess or monitor more closely existing technical assistance projects.

Next component is the process of prioritization and conduct of USOAP CMA activities

This process covers activities conducted by ICAO Monitoring and Oversight Section (CMO) and ICAO Regional office (ICAO ROs) to identify deficiencies in a State and to assess and elaborate Finding and Recommendation (F&Rs) and Significant

Ref:ASCOS_WP2_loA_D2.3Page:121Issue:1.0Classification:Restricted

Safety Concerns (SSCs). These are: Comprehensive Systems Approach (CSA) Audits, Safety Audits and ICAO Coordinated Validation Missions (ICVMs).

The objective of a CSA Audit is to determine a State's capability for safety oversight by assessing the effective implementation of the eight CEs of the safety oversight system and the status of the State's implementation of all safety-related ICAO SARPs, associated procedures, guidance material and best safety practices. The objective of a Safety Audit is to an audit of its current safety oversight system.

The objective of an ICVM is to assess and validate the status of corrective actions or mitigating measures taken by a State to address previously identified F&Rs, including SSCs. ICVMs also include on-site guidance provided to the State in resolving remaining deficiencies.

The final component is the process of update of Lack of Effective Implementations (LEIs) and status of Significant Safety Concerns (SSCs).

Estimation of collected safety information enables ICAO to continuously update the Lack of Effective Implementation (LEI) of the safety oversight capability for each State. The LEI is based on the number of applicable non-satisfactory Protocol Questions (PQs). The LEI for each State may be updated based on the information received through Mandatory Information Requests (MIRs) and Corrective Action Plans (CAPs) indicating progress made in resolving Findings and Recommendations (F&Rs) and Significant Safety Concerns (SSCs).

If an F&R is considered to be an immediate safety risk to international civil aviation, the State will be informed of the identification of an SSC and requested to take immediate mitigating or corrective actions. If appropriate evidence is not provided by the State that such actions have been taken within a specified timeframe, all Member States will be notified of the SSC through the CMA online framework.

State obligations under the USOAP CMA

Member States shall sign USOAP CMA Memorandum of Understanding (MOU) with ICAO to confirm their full support of the USOAP CMA process and to commit to actively participating in all USOAP CMA activities, including the provision of information through the CMA online framework. Member States should secure adequate resources to meet all the conditions of the MoU.

Each State is responsible for identifying one or more qualified National Continuous Monitoring Coordinators (NCMCs) to act, on an on-going basis, as primary point(s) of contact for all USOAP CMA processes and activities.

The NCMC is responsible for maintaining and updating the information to be provided by the State to the CMO Section on an on-going basis, including:

- SAAQ,
- CCs,
- State responses to PQs,

Ref:ASCOS_WP2_loA_D2.3Page:122Issue:1.0Classification:Restricted

- State responses to MIRs,
- CAPs to resolve F&Rs,
- Mitigating measures taken by the State in response to SSCs,
- The latest information regarding the SSP, and
- Other relevant safety information, as requested by ICAO.

The NCMC shall coordinate the completion and ongoing update of the CCs in order to provide the CMO with information regarding the implementation of provisions of the relevant Annexes to the Convention.

Perspectives of the use of USOAP CMA

The effective SSP implementation is one of the near-term ICAO Global Aviation Safety Plan (GASP) [7] objectives. It is a gradual process requiring time, depending on complexity of air transportation and applicable to States with mature safety oversight systems. Since 14 November 2013 the overarching safety management provisions of the Annexes have been transferred into a new **Annex 19**[2]. It is supported by guidance of Safety Management Manual (Doc 9859) which 3rd edition of 2013 was substantially enhanced. The four components of the SSP were elevated to the status of ICAO Standard to match the SMS framework. The SSP implementation timeline was organised into four phases [6]:

- Phase 1 (12 months) identification of SSP place holder, executives, establishing SSP teams, perform gap analysis, develop implementation plan, establish coordination mechanism, develop documentation.
- Phase 2 (12 months) establish a legislative framework, document safety management responsibilities, define
 State safety policy and objectives, establish accident investigation process, basic enforcement, provide for safety oversight, promote SMS education.
- Phase 3 (24 months) promulgate enforcement policy, develop harmonised legislation requiring SMS, establish safety data collection and exchange system, establish State SPIs and target levels.
- Phase 4 (24 months) review and agree upon service provider's SPIs, incorporate SMS and SPIs into routine surveillance programme, implement voluntary/confidential safety reporting, establish lower consequence indicators, promote safety information exchange among organisations across ICAO, prioritise inspections based on the analysis of safety risk, establish internal review mechanism

Starting May 14th, 2014, ICAO is going to monitor Member States' implementation of SSP through the Universal Safety Oversight Audit Programme (USOAP) [2]. The necessary input is supposed to be acquired through the adjusted USOAP State Aviation Activity Questionnaire (SAAQ) grouped in alignment with phased-approach implementation and Protocol Questionnaires (PQs) as appropriate [10].

The Memorandum of Cooperation between EU and ICAO of 2010 [14] provided a framework for enhanced cooperation including coordination of respective audits and inspection programmes avoiding duplication of efforts.

The implementation of the USOAP CMA provides ICAO effective system of continuous monitoring and management in the field of civil aviation. The system allows carrying out both corrective actions and improvement actions.

Ref:ASCOS_WP2_IoA_D2.3Page:123Issue:1.0Classification:Restricted

Appendix F Safety Database

Fundamentals of Safety Database

Sound management of the organization's databases is fundamental to ensure effective and reliable safety analysis of consolidated sources of data. Depending on the size and complexity of the organization, system requirements may include a range of capabilities to effectively manage safety data. In general, the system should:

- a) include a user friendly interface for data entry and guery;
- b) have the capability of transforming large amounts of safety data into useful information that supports decision making;
- c) reduce workload for managers and safety personnel;
- d) operate at a relatively low cost.

The functional properties and attributes of different database management systems vary, and each should be considered before deciding on the most suitable system. Basic features should enable the user to perform such tasks as:

- a) log safety events under various categories;
- b) link events to related documents (e.g. reports and photographs);
- c) monitor trends;
- d) compile analyses, charts and reports;
- e) check historical records;
- f) share safety data with other organizations;
- g) monitor event investigations;
- h) monitor the implementation of corrective actions.

Safety management relies on measurement of safety indicators and monitoring. A data warehouse model facilitates performing analyses. Whereas typical database design purpose is to support On-Line Transaction Processing (OLTP), which requires primarily maintaining consistency of constantly changing data and reducing time of finding required information, while the data warehouses are designed to support On-Line Analytical Processing (OLAP), that may require pre-processing of data to provide more sophisticated information, storing historical data to find trends and patterns or mapping data for data mining. Data warehouses store integrated data, often originating from other databases, store data from long time periods, its size are measured in Terabytes (currently). It is expected that existing data are rarely modified, but regularly new data are added. It is expected that sophisticated queries can be processed in a short time. The abovementioned properties are useful for safety monitoring, as safety data originate from different sources, the data cover long time periods and safety analyses require finding trends and patterns in the safety performance.

Ref:ASCOS_WP2_loA_D2.3Page:124Issue:1.0Classification:Restricted

Overview of Safety databases

The purpose of this section of the document is to gain an insight in the context (i.e. the current environment and initiatives) in which the proposals of ASCOS are to operate. With such an insight, one can then tailor the implementation of the ASCOS proposals to ensure any proposal is both achievable and provide net benefit.

The context is characterised, for the purpose of discussing implementation, by inspection and analysis of each of the following key points;

- Aircraft accident analysis reports; There is wide recognition in the aviation industry that many lessons can and should be learnt from the analysis of accident reports.
- The annual statistical reviews of Global Accidents by ICAO, EASA, UK CAA and Boeing.
- The activity of The Safety Management International Collaboration Group (SM ICG); founded by the United States Federal Aviation Administration (FAA), the European Aviation Safety Agency (EASA) and Transport Canada Civil Aviation it is a joint cooperation between many regulatory authorities for the purpose of promoting a common understanding of safety management principles and requirements and facilitating their implementation across the international aviation community.
- Review of the UK CAA Publication (CAP) 1036. It is also possible to detect weaknesses in the
 implementation of some fundamental supporting tasks such as the variability in the reporting of
 accidents. ICAO USOAP provides an overall view of the maturity of the State Safety Programmes for
 each ICAO region.

Accident reporting criteria are not consistent throughout the world so the number of factors assigned to accidents can vary widely. As with all statistics, care must be taken when drawing conclusions from these reports.

Safety Data Collection and Processing Systems (SDCPS)

This section provides an overview of existing Safety reporting systems (International Confidential Aviation Safety Systems), in particular US and European systems.

Annex 13 to the Chicago convention stipulates that Contracting States "establish and maintain an accident and incident database to facilitate the effective analysis of information on actual or potential safety deficiencies obtained, including that from its incident reporting systems, and to determine any preventive actions required" [1], and establish a mandatory and voluntary incident reporting systems to facilitate gathering of information on actual or potential safety deficiencies [1]. Safety databases may include the following data [1]:

- Accident investigation data;
- Mandatory incident investigation data;
- Voluntary reporting data;
- Continuing airworthiness reporting data;
- Operational performance monitoring data;
- Safety risk assessment data;

Ref:ASCOS_WP2_IoA_D2.3Page:125Issue:1.0Classification:Restricted

- Data from audit findings/ reports;
- Data from safety studies/ reviews;
- Safety data from other States, Regional Safety Oversight Organizations or Regional Accident & Incident Investigation Organizations; etc.

ICAO ADREP (Accident/incident data reporting)

The Accident/Incident Data Reporting (ADREP) system was established in 1976 and has since evolved to meet changes in aviation industry and ICT technology. The system gathers and stores occurrence data to assist the Contracting States in improving aviation safety. It is operated and maintained by International Civil Aviation Organisation (ICAO). The Contracting States of the Convention are required to report to ICAO the information on all aircraft accidents which involve aircraft of a maximum certificated take-off mass of over 2 250 kg and incidents involving aircraft of mass over 5700 kg.

ECCAIRS (European Co-ordination centre for Accident and Incident Reporting System)

ECCAIRS is a co-operative network of European Transport Authorities and Accident Investigation Bodies. Its mission is "to assist National and European transport entities in collecting, sharing and analysing their safety information in order to improve public transport safety" and prevent future accidents. The issue that most EU member states were collecting safety data that were not compatible was addressed. The project started operation in the early nineties and is managed by the Joint Research Centre of the European Commission on request of the Directorate General for Energy and Transport (DG TREN). In EU, directive 2003/42/EC of the EU Parliament stipulates that the member states designate competent authorities to collect and process reports on occurrences in aviation. ECCAIRS allows, through standardisation of reporting data to integrate, exchange and compare data from different member states. ECCAIRS superseded previous national reporting systems, e.g. Finnish VASA.

At the time of writing this report, the current version of the software was 5. ECCAIRS software allows creating, maintaining and deploying a repository of accident and incident reports. It is available free of charge.

The applications comprising the suite are as follows:

- Data entry and retrieval used to enter accident/incident data in repository. The browser is a front end for ECCAIRS repository, allowing data exploration. The Query Builder allows an authorised user to add and modify stored information. The ECCAIRS system implements ICAO ADREP taxonomy standards, as well as other safety taxonomies public transport domains.
- Analysis software of stored information
- Utilities useful for the system users, not found in the standard software, e.g. TARGA fills-in aircraft characteristics.
- System tools for maintenance of ECCAIRS,
- Data integration at national or European level,

Ref:ASCOS_WP2_IoA_D2.3Page:126Issue:1.0Classification:Restricted

Data dissemination at national or European level.

Outputs are stored in e5f file format. ECCAIRS software is in use in many reporting systems worldwide.

AIDS - Accident/Incident Data Systems

Accident/Incident Data Systems (AIDS) is run by the FAA. Data records stored contain information on general aviation and air carrier incidents since 1978. The database is complementary to the NTSB accident database which does not contain incidents.

AR - Air Registry

FAA Air Registry (AR) database contains information on all civil aircraft registered in the United States. The database is updated in real time.

ASRS – Aviation Safety Reporting System

The U.S. Aviation Safety Reporting System (ASRS) reporting system began operation on 15 April 1976. Since its foundation, the system has been emulated in other countries and other industries. The ASRS purpose is to learn about air transport safety vulnerabilities and gain better understanding of causes of human errors. It is complementary to the mandatory, monitoring and statistical systems. The idea behind the ASRS is that knowledge about safety in air transport can be improved by asking the participants, who are willing to share their knowledge if their identities remain undisclosed. The properly structured reporting system should be confidential, voluntary and non-punitive and can be used by any person. The FAA asked NASA, as independent and highly respected entity to operate the system, since it was seen that the aviation community would be disinclined to trust and use the system due to FAA's enforcement and regulatory role. Important safety information gathered by the system (after de-identification) is open to all users across the industry. Safety alerts and results of data analyses are disseminated to the key organisations and stakeholders in the U. S. aviation.

The output of the system includes:

- Alert Bulletins on aircraft design faults, airport facilities, airspace design, navigational equipment, procedures and other issues that may compromise safety addressed to the FAA and aviation community.
- For Your Information Notices, messages on topics as above to the FAA and aviation community.
- Quick Response Studies are carried out to support the U.S. government organisations on request.
- Operational Research returns information to stakeholders and consequently improve safety.
- Database Search can be carried out on request at no cost under Freedom of Information Act provisions.
- Publications include a monthly safety bulletin CALLBACK and periodic Directline.

Ref:ASCOS_WP2_IoA_D2.3Page:127Issue:1.0Classification:Restricted

 Other staff members' activities include participation in important aviation events, meetings and conferences. Twice a month, a teleconference takes place between ASRS and FAA office of safety on most important alerts and issues.

BTS - Bureau of Transportation Statistics

U.S. Bureau of Transportation Statistics database contains traffic and capacity statistics concerning individual air carrier operations. BTS is a statistical agency under the Department of Transportation.

NMACS - Near Midair Collision System

Near Midair Collision System is a database containing information on incidents where a possibility of collision took place with proximity of 500ft (152,4 m) or less and incidents reported by pilots or flight crew members when hazard of collision existed. The reports are investigated by FAA inspectors in cooperation with traffic controllers. The results of investigations are used for development of programs, policies and procedures in air transportation system.

NTSB Accident/incident reporting system

The U.S. National Transport Safety Board (NTSB) has been recording civil aircraft accident since 1967. The NTSB is conducting investigations of all accidents and incidents involving civil aircraft in the U.S. and also many U.S. owned, registered or manufactured aircraft abroad. NTSB Accident/incident database is an official repository of aviation accidents, incidents and casual factors as well as annual reports, reviews and reports from investigations (both preliminary and final) carried out by the NTSB.

RWS - Runway Incursion Database

The U.S. Runway Incursion Database contains information on events, both accidents and incidents, where aircraft, vehicle or person was present on a protected area used for take-off and landing operations. The records date back to 2005. The events are reported by an air traffic control tower responsible for given area.

WAAS - World Aircraft Accident Summary

World Aircraft Accident Summary (WAAS) was produced by Airclaims Ltd. on behalf of the British Civil Aviation Authority. The database includes brief details on all known major operational accidents worldwide that involved air carriers and larger aircraft. Presented data sources include both unofficial sources (press releases) and official reports from investigation.

ASIAS – Aviation Safety Information Analysis and Sharing

The Aviation Safety Information Analysis and Sharing (ASIAS) program was created by the Federal Aviation Administration (FAA) which promotes open exchange of information concerning safety to perform integrated searches across mainly U.S. databases. The databases that can be accessed include:

Ref:ASCOS_WP2_loA_D2.3Page:128Issue:1.0Classification:Restricted

- AIDS (incidents only),
- AR
- ASRS,
- BTS,
- NMACS,
- NTSB Aviation Accident and Incident Data System, as well as recommendations with FAA responses,
- RWS,
- WAAS.

FDM data of the US operators can be found in the ASIAS warehouse.

SAIRS - Singapore Aviation Safety Accident/Incident Reporting System

The restructured system framework SAIRS began operation in the beginning of 2010. The SAIRS Form is built on Dexter. CAAS (Civil Aviation Authority of Singapore) is managing the system. ECCAIRS was adopted as a basis operating platform for standardisation of safety data format with that of ICAO ADREP taxonomy. Safety data is validated prior to entry into database. SAIRS integrates safety data from Aerodrome and Air Navigation Service Provider.

Others

While many of the 191 countries that signed the Chicago Convention on International Civil Aviation organised reporting systems, both voluntary and mandatory, their importance is only local and insignificant from the project point of view.

Framework of Safety Data Management

Safety system quality depends on the safety data management. The scope of data management is the organisation of processes to assure that the necessary, reliable data are available and that the access to the data is efficient. After collecting safety data through various sources, organizations should then perform the necessary analysis to identify hazards and control their potential consequences.

Safety data management process elements are as follows [35]:

1. Definition of data needs.

Data to be collected, including SPIs need to be defined and a plan for data collection and use needs to be elaborated. Separate plans for data collection are needed on the service provider level, State level and EU level. Potential users (public, organisation employees, or external entities) need to be determined. The data needs and user requirements provide input for the database design.

2. Design of data architecture and data structure, including aggregation of data from different sources.

Ref:ASCOS_WP2_IoA_D2.3Page:129Issue:1.0Classification:Restricted

Requirement analysis is necessary to effectively design and adjust the database. Data architecture needs to be adapted to both stored data and its planned use and update frequency. A database supports performing analyses by providing pre-processed data for immediate access.

3. Definition of format and standards to be used.

Standardisation of data and formats is needed to compare and exchange data between databases and data from different sources. Individual service providers must adapt their data format to requirements elaborated on the EU and state level. A common taxonomy need to be used (preferably ICAO ADREP). Should standardised data be unavailable, it may be necessary to create data mapping to allow data integration from various sources.

4. Development of data collection tools.

The tools facilitating collection of data need to be easy to access, while preventing unauthorised persons to access the data. Ease of use should ensure that minimum effort is needed to fill a data form, while format restrictions should prevent invalid data to be entered.

5. Sharing of safety data with other stakeholders.

The aviation community should share safety data. Shared data need to be de-identified. The foundation of the ASRS was a result of the conclusion that safety data must be shared to prevent repeating the same mistakes. A common taxonomy and standardisation of formats is important to achieve the feasibility of the data exchange. Currently available tools allow integrating data from various sources.

6. Addressing security and data protection.

Collected data requires protection from unauthorised use. Regulations on national level in different States stipulate the need to protect personal information. The basic concepts regarding security are secrecy, integrity and availability. Secrecy means that a user should only see what he is authorised to see. Integrity means that the user cannot modify data if he is not authorised. Availability means that a user can read and modify data if he is authorised. Personal data protection necessity is stipulated by regulations on the national level. Means of protection must include control of access to database by the software and also physical protection of data storage is required. A proper security policy must be elaborated and implemented to address security issues. See also chapter 3.7 in this document.

7. Data management during the database life-cycle, including adjustment.

A storage plan needs to assure that enough capacity will be provided. Data storage should be adjusted as the usage profile changes during the database lifetime. A backup plan is required to ensure continuous data availability, protect from data loss and to provide redundancy in case of database malfunctions.

Appendix A for ASCOS D2.3

WP2.3 Process for Safety Performanc Monitoring (lead participant = IoA)

ASCOS will progress beyond the state-of-the-art by developing and validating a continuous monitoring process in which safety performance indicators for each stakeholder will be linked with precursors for all the main operational issues for commercial air transport operations as identified in the European Aviation Safety Plan (EASP) framework [2, 10]. This task will investigate how CMA can be used as integral part of the life cycle processes for continued airworthiness of aircraft, and maintenance of certificates for air navigation service providers, operators, and manufacturers. ASCOS will investigate if and how flight data obtained by Flight Data Monitoring (FDM) and Flight operations Quality Assurance (FOQA) can be used to enhance the safety benefits of a multi-stakeholder CMA in aviation. [314299 ASCOS - Workplan table - 2012-05-16 15:09 - Page 8 of 29]

431		Poor application of T/O & RTO procedure, computation of T/O parameters					V	
432		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Aircraft door system and / or components		V				
433		Flaws in aircraft system maintenance process definition - Aircraft door system and / or components		V				
434		Long / floating flare						٧
435		Lack of adherence to ICAO Annex 14 and related documents in terms of airside lights distribution	V					
436		Lack of adherence to ICAO Annex 14 and related documents in terms of nonrestricted view on airsite from TWR	V					
437		Lack of adherence to the current technology standards in terms of flight safety supporting systems. Lack of Runway Conflict Warning System.	V					
438		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - RCWS	V					
439		Lack of adherence to the SOP in terms of critical maneuvre execution - flare		V				
440		Extreme operation condition / poor maintenance quality / advanced life lenght		V				
441		Failure to arm ground-spoilers		V				V
442		Incorrect or inappropriate radar vectoring by ATC (i.e., below MVA and/or toward high terrain)			V			
443		Premature descent to DA(H) before G/S intercept or premature descent to MDA(H) before final-descent-point / FAF			V			
444		Premature descent below MDA(H) before reaching the visual-descent-point (VDP)			V			
445		Flight below desired flight path during initial and/or final approach			V			
446		Continued approach, when below DA(H) or MDA(H), after loss of visual references			V			
447		Late or inadequate response to MSAW warning			V			
448		Failure to go-around, when so required			V			
449		Failure to follow published missed-approach procedure			V			
450		Lack of adherence to the current technology standards in terms of flight safety supporting systems. Lack of MSAW system.			V			
451		Lack of adherence to emergency procedures - flight deck smoke procedure		V				
452		Lack of adherence to AFM in terms of emergency procedures - windshear recovery		٧				
453		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - MSAW System			V			
454		Lack of adherence to the current technology standards in terms of flight safety and efficiency - engines location.		٧				
455		Lack of adherence to SOP. Lack of awareness and immidiate answer on supporting systems warning. MSAW warning.			V			
456		Flaws in manufacturer quality control process - CPCS system and / or components		V				

	Safety Performance	Precursors		Ор	eration	al issu	e	
No.	Indicators	PIECUISOIS	1	2	3	4	5	6
457		Flaws in aircraft system maintenance process definition - CPCS system and / or components		V				
458		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - CPCS system and / or components		V				
459		Incorrect use of automation - CPCS		V				
460		Inadequate stall recovery procedure for the aircraft	V				٧	
461		Late thrust reduction or power-on touchdown		V				V
462		Use of non-standard phraseology by pilot flying (PF) and/or pilot not flying (PNF)		V				
463		Lack of adherence to SOP in terms of necessary amount of fuel		V				V
464		Lack of adherence to AFM in terms of emergency procedures - engine failure		٧				
465		Flaws in manufacturer quality control process - TOCW system components					٧	
466		Lack of adherence to SOP for approach and landing		V				
467		Gross error in takeoff weight entry and/or in V1 / VR speeds assessment		V				
468		Flaws in manufacturer quality control process - Stickshaker system components					٧	
469		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - ACAS system components				V		
470		Lack of adherence to the current technology standards in terms of flight safety supporting systems. Lack of GPWS			V			
471		Inappropriate visual avoidance maneuver				٧		
472		Lack of adherence to the current technology standards in terms of flight safety supporting systems. Lack of ACAS installed on aircraft.				V		
473		Late or inadequate response to ACAS warning				V		
474		Taxiing without clearance		V				
475		Flaws in aircraft system maintenance process definition - GPWS system components			V			
476		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - GPWS system components			V			
477		Flaws in manufacturer quality control process - GPWS system components			V			
131	A proper means to identify future risks is set-up and altered when deemed necessary	Pilot tiredness - Inadequate workload distribution	V	V	V	V	٧	٧
132		Flaws in pilot requirements definition process and/or training methodology	V	V	V	٧	٧	V
133		Flaws in maintenance technician / airworthiness specialist requirements definition process and/or training methodology	V	V	V	V	٧	V

218		Flaws in aircraft system maintenance process definition - ECAM (or similar) system components.		V				
219		Unintuitive and / or error prone system manual - Engine anti-icing system		V				
220		Lack of adherence to the current technology standards in terms of flight safety supporting systems. Lack of ECAM.		V				
221		Flaws in manufacturer quality control process - ECAM (or similar) system components.		V				
222		Flaws in Airspace and Air Traffic planning procedures design process				V	٧	
223		Lack of adherence to SOP for GND movements. Lack of awareness in terms of current situation on the airsite or / and aircraft / vehicle proximity	V				V	
224		Flaws in aircraft system maintenance process definition - Electrical wiring System		V			٧	
225		Flaws in aircraft system maintenance process definition - Engine combustor		V				
226		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Engine combustor		٧				
227		Flaws in manufacturer quality control process - Engine combustor		V				
228		Flaws in aircraft system maintenance process definition - Engine turbine components		V				
229		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Engine turbine components		٧				
230		Flaws in manufacturer quality control process - Engine turbine components		V				
231		Lack of adherence to SOP for take-off procedure in terms of determining of aircraft configuration.					٧	
232		Lack of adherence to SOP for take-off procedure in terms of checking take-off configuration before application of take-off power.					V	
233		Incorrect stab-trim setting	_				٧	
234		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Ground navigational systems and components (e.g. ILS)			٧			

	Safety Performance	Drocursors		Op	eration	al issu	e	
No.	Indicators	Precursors	1	2	3	4	5	6
235		Failure to check navigation accuracy before approach			V			
236		Lack of adherence to SOP. Lack of awareness and immidiate answer on supporting systems warning. Navigational aid failure.	1		V			
237		Not recognized ground Navaids System failure not reflected in NOTAM messages			V			
238		High energy approach due to lack of adequate planning or due to challenging design of STAR (high fix-crossing-altitudes,) or challenging ATC instructions (late descent, vectors, altitude or speed restrictions,)		V				V
239		Late deceleration and configuration set-up for approach and landing		V				V
240		Flaws in aircraft system maintenance process definition - Ground navigational systems and components (e.g. ILS)	İ		V			1
241		Flaws in manufacturer quality control process - Ground navigational systems and components (e.g. ILS)			V			
242		Inadvertent deviation from cleared taxi route	V					
243		Lack of adherence to SOP for AIR operations in terms of controller error in approach clearence instruction			V			
244		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Hydraulic system components		V			V	
245		Flaws in aircraft system maintenance process definition - Hydraulic System		V			V	
246		Flaws in aircraft system maintenance process definition - Communication equipment systems and components.	1			V	٧	
247		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Communication equipment systems and components.				٧	٧	
248		Flaws in manufacturer quality control process - Communication equipment systems and components.				V	V	
249		Tactical or / and Planning Controller tiredness - Inadequate workload distribution				V		
250		Flaws in Tactical or / and Planning Controller requirements definition process and/or training methodology				V		
251		Navigation deviation				٧	٧	
252		Poor application of T/O & RTO procedure, aircraft handling					V	
253		Inadequate maintenance of RWY. Lack of adherence to ICAO Annex 14 in terms of RWY surface condition. Snow / ice presence / or runway surface friction rate below minimum		٧			٧	٧
254		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - Fire deection system components		V			٧	
255		Takeoff without clearance	V				٧	
256		Landing without clearance	V		_		V	
257		Inadequate certification process and / or flaws in methodology concerning verification of the system / product compliance with requirements - marshalling/rolling/taxiing control related system and components (incl. brake)	V				V	
258		Poor application of T/O & RTO procedure, failure recognition and preparedness					٧	
259		Flaws in aircraft system maintenance process definition - Fire detection system components		V			٧

Appendix B for ASCOS D2.3

WP2.3 Process for Safety Performanc Monitoring (lead participant = IoA)

ASCOS will progress beyond the state-of-the-art by developing and validating a continuous monitoring process in which safety performance indicators for each stakeholder will be linked with precursors for all the main operational issues for commercial air transport operations as identified in the European Aviation Safety Plan (EASP) framework [2, 10]. This task will investigate how CMA can be used as integral part of the life cycle processes for continued airworthiness of aircraft, and maintenance of certificates for air navigation service providers, operators, and manufacturers. ASCOS will investigate if and how flight data obtained by Flight Data Monitoring (FDM) and Flight operations Quality Assurance (FOQA) can be used to enhance the safety benefits of a multi-stakeholder CMA in aviation. [314299 ASCOS - Workplan table - 2012-05-16 15:09 - Page 8 of 29]

Table of Contents

Β.	Details of Step 1 to 8	2

Step 2 – Association of precursors and defences/controls when possible

Occurrences (Uneventful No. Deviations No. Deviations No. Defences/CONTROLS (Procedural/Flight Path)

Events)		(Procedural/Flight Path)		I
PRECURSORS				DEFENCES/CONTROLS
Occurrences (Uneventful Events)	No.	Deviations (Procedural/Flight Path)	No.	Prevention (Detection/Recovery)
Runway confusion	1			Pilot training, signs on the runway
Runway incursion	2			Airport security
Takeoff or landing on taxiway	3			Airstrip markings, ATM guidance, ILS operation
Airport confusion	4			Airport beacon, ATM guidance, Airport tower, navigation aids, GPS, TACAN
Wildlife incursion	5			Airport security program, active observation and deterrence of wildlife
Adverse weather / poor visibility conditions / darkness	6			Pilot training incl. IFR flights, ATM guidance, navigation aids, pilot training
Taxiway confusion	7			Tower guidance, taxiway marking, pilot training
Emergency landing	8			Aircraft maintenance, A, B, C, D-checks
Taxiway incursion	9			Airport security
Stand confusion	10			Tower guidance, taxiway marking, pilot training
inadequate anti-ice fluid holdover Time (HOT)	11			Maintenance staff training
Contaminated wing	12			Maintenance staff training, aircraft visual check prior to take-off
Continued unstabilized approach (failure to comply with go-around criteria and policy)	13			Pilot training, aircraft tracking by airport tower
AOA prevents missed approach	14			Pilot training
System failures that may affect braking devices (ground spoilers, brakes / autobrake, thrust reversers)	15			Aircraft maintenance checks
Gross loading error	16			Ground crew training, pilot inspection
Cargo loading unsecured / shift	17			Ground crew training, checklists, procedures
Convective weather encounter	18			Flight plan, weather forecast, weather radar, ATM guidance

Occurrences (Uneventful Events)	No.	Deviations (Procedural/Flight Path)	No.	DEFENCES/CONTROLS
Extreme turbulence encounter	19			Flight plan, weather forecast, weather radar, ATM guidance
Extreme icing conditions	20			Flight plan, weather forecast, weather
encounter				radar, ATM guidance
Windshear encounter	21			Flight plan, weather forecast, weather radar, ATM guidance
Volcanic ash encounter	22			Volcano activity observation, Flight plan, ATM guidance
Mountain wave / vortices encounter	23			Pilot training, Flight plan, weather forecast, weather radar, ATM guidance
Wake turbulence encounter	24			Pilot training, Flight plan, weather forecast, weather radar, ATM guidance
System failure affecting aircraft configuration, controllability and/or flying qualities	25			Aircraft maintenance checks, fail-safe design
System failure affecting the operation of primary instruments / displays or standby instruments	26			Aircraft maintenance checks, fail-safe design
Failures resulting in a non- standard fuel distribution	27			Aircraft maintenance checks, aircarft design
Uncommanded thrust asymmetry	28			Aircraft maintenance checks, aircarft design
In-flight smoke / fumes / fire (in cockpit, cabin, cargo) events that could affect the crew ability to conduct their duties and/or the aircraft controllability	29			Aircraft maintenance checks, aircarft design, security, maintenance staff training,
Adverse weather / poor visibility conditions	30			Pilot training, weather forecast, flight plan, ATM guidance, navigation aids
Extreme icing condition and / or heavy snow. Break in airport operation due to adverse weather or / and necessity of RWY surface maintenance.	31			Weather forecast, flight plan, navigation aids, Tower guidance
Convective weather / turbulence / windshear or crosswind conditions during take-off	32			Weather forecast, flight plan, navigation aids, Tower guidance
Cabin pressure drop as a result of aircraft structural failure	33			Aircraft maintenance checks, fail-safe design
Bird strike	34			Airport wildlife deterrence program
Turbulence encounter	35			Pilot training, wather forecast, flight plan,

Occurrences (Uneventful Events)	No.	Deviations (Procedural/Flight Path)	No.	DEFENCES/CONTROLS
				ATM guidance, navigation aids
Flight crew incapable in result of extreme turbulence	36			Seat belts, pilot physical and health tests,
Inadequate fuel quality / type	37			Daily fuel quality checks at FBO, tank
				markings, ground crew training
Crew is incapable in result of extreme turbulence	38			Seat belts, crew physical and health tests,
Contaminated Runway	39			Runway state monitoring, Airport safety program
Engine suffers severe surge	40			Pilot training, engine control system, engine design, engine maintenance
Severe failure of all engines on	41			Pilot training, engine control system,
transoceanic route or over rarely populated area				engine design, engine maintenance
Convective weather / turbulence / windshear / crosswind / icing conditions encounter during	42			Pilot training, weather forecast, flight plan, ATM guidance, navigation aids
approach and landing	42			Control designs with the residual to the
Crew is incapable in result of shock related to hard landing	43			Seat design, pilot physical tests
Missed approach execution	44			Pilot training, weather forecast, flight plan,
necessary after prolonged flight due to e. g. extreme weather				ATM guidance, navigation aids
Adverse weather in terms of heavy rain or icing conditions resulted with decreased RWY surface friction rate	45			Runway state monitoring, Airport safety program, weather forecast
Cautions / warnings (genuine or spurious) that may lead to a low-speed or high-speed rejected take-off	46			Avionics maintenance, design
Hard landing	47			Pilot training, ILS, Tower guidance,
Rejected takeoff (whether initiated below or above 100 kt)	48			Avionics maintenance, design
(+) due to an aircraft system failure including engine				
Severe structural failure of aircraft or / and its critical	49			Pilot training, ILS, Tower guidance, fail-safe design
systems resulted from design load exceeding during touchdown				ucsigii

Occurrences (Uneventful Events)	No.	Deviations (Procedural/Flight Path)	No.	DEFENCES/CONTROLS
GPWS / TAWS alert / warning	50			Pilot training, ATM and tower guidance,
(genuine or spurious)				flight plan, Navigation aids
MSAW warning	51			Pilot training, ATM and tower guidance,
				flight plan, Navigation aids
Other cases of reduced terrain	52			Pilot training, ATM and tower guidance,
separation				flight plan, ILS
Prolonged loss of	53			Communication Systems maintenance and
communications (PLOC) between				design,
pilot and controller(s)				
Low-energy state during	54			Pilot training, fly-by-wire/light
approach				
Land short (runway undershoot)	55			Pilot training, ILS, Tower guidance
event	33			Thot training, iES, Tower galactice
Low altitude pattern following a	56			Pilot training, Tower guidance, TCAS
go-around	30			Thot training, Tower guidance, Teas
Inappropriate low altitude	57			Pilot training, Tower guidance, TCAS
	37			Filot training, Tower guidance, TCAS
maneuvering	58			Dilat training flight planning
Low-on-fuel condition / fuel starvation	36			Pilot training, flight planning, communication with ATM
	59			
Crew incapacitation resulted from	39			Pilot health monitoring
illness (e.g. food poisoning)	60			Durana state manifesia
Natural or artificial obstacle on	60			Runway state monitoring
runway course	C1			Maintanana ataff tuaining databasa
Error in preparation of database for FMS	61			Maintenance staff training, database
	62			design, backups, database backlogs
Ground Navigational Aid failure	62			Equipment maintenance
Landing gear retraction failure	63			Undercarriage maintenance
Frontal surface encounter	64			wather forecast, pilot training, ATM
				guidance
Convective weather / turbulence	65			Tower guidance, wather forecast, pilot
/ windshear encounter conditions				training
during landing				
Midair collision	66			ATM guidance, radar, pilot training,
			-	procedures, transponder
Collision with ground obstacle	67			Runway state monitoring, TCAS, pilot
			+	training
Inadequate NOTAM information	68			ground installation maintenance
concerning ground navigational				
aid failure			1	
Inadequate navigational chart	69		1	air carrier organisation, pilot training
TCAS RA events (genuine or	70			Pilot training, navigational aids, ATM

Occurrences (Uneventful Events)	No.	Deviations (Procedural/Flight Path)	No.	DEFENCES/CONTROLS
spurious)				guidance
Airspace infringement	71			ATM guidance, radar, pilot training,
				procedures, transponder, air defence
Other cases of loss of separation	72			ATM guidance, radar, pilot training,
				procedures, transponder
Prolonged loss of communication (PLOC) between pilot and controller	73			Communication Systems maintenance and design,
Failures affecting TCAS operation	74			TCAS equipment maintenance
Convective weather - heavy rain resulted with wet RWY surface	75			runway state monitoring, airport safety program
Convective weather encounter in traffic intensive airport proximity	76			Weather forecast, Towe and ATM guidance
Engine failure	77			Engine maintenance, checks, design, pilot training
System failure affecting the operation of primary instruments / displays or standby instruments - ADS-B System	78			Display maintenance, checks, design, pilot training
Cabin pressure drop as a result of pneumatic system failure	79			Aircraft systems maintenance, checks, design
Tire burst	80			Tire maintenance, replacement, runway state monitoring
System failure affecting the operation of primary instruments / displays or standby instruments	26			Aircraft systems maintenance, checks, design
